1 Introduction

1.1 Purpose

This document describes the minimum capabilities and characteristics that a video streaming device must support to comply with the USB Video Class specification.

It defines and standardizes video streaming functionality on the USB, and contains all necessary information for a designer to build a USB-compliant device that incorporates video streaming functionality. It specifies the standard and class-specific descriptors that must be present in each USB video function. It further explains the use of class-specific requests that allow for full video streaming control.

Devices that conform to this specification will be referred to as USB Video Class devices.

1.2 Scope

The Video Device Class Definition applies to all devices or functions within composite devices that are used to manipulate video and video-related functionality. This would include devices such as desktop video cameras (or "webcams"), digital camcorders, analog video converters, analog and digital television tuners, and still-image cameras that support video streaming.

1.3 Related Documents

USB Specification Revision 2.0, April 27, 2000, www.usb.org
USB Device Class Definition for Audio Devices, Version 1.0, March 18, 1998, www.usb.org
Interface Association Descriptor ECN, www.usb.org

1.4 Document Conventions

The following typographic conventions are used:

- Italic Documents references
- Bold Request fields
- Uppercase Constants

The following terms are defined:

- Expected
  a keyword used to describe the behavior of the hardware or software in the design models assumed by this specification. Other hardware and software design models may also be implemented
- May
  a keyword that indicates flexibility of choice with no implied preference.
- Shall/Must
  keywords indicating a mandatory requirement. Designers are required to implement all such mandatory requirements.

- Should
  a keyword indicating flexibility of choice with a strongly preferred alternative. Equivalent to the phrase is recommended.

1.5 Terms and Abbreviations

Term	Description
Configuration	A collection of one or more interfaces that may be selected on a USB device.
Control	A logical object within an Entity that is used to manipulate a specific property of that Entity.
CT	Camera terminal.
Descriptor	Data structure used to describe a USB device capability or characteristic.
Device	USB peripheral.
Driver	Host software that connects other drivers, DLLs, or applications to the USB.
Endpoint	Source or sink of data on a USB device.
Entity	A Unit, Terminal or Interface within the video function, each of which may contain Controls.
GUID	Globally Unique Identifier. Also known as a universally unique identifier (UUID). The Guidgen.exe command line program from Microsoft is used to create a GUID. Guidgen.exe never produces the same GUID twice, no matter how many times it is run or how many different machines it runs on. Entities such as video formats that need to be uniquely identified have a GUID. Search www.microsoft.com for more information on GUIDs and Guidgen.exe.
Host	Computer system where a Host Controller is installed.
Host Controller	Hardware that connects a Host to the USB.
Host Software	Generic term for a collection of drivers, libraries and/or applications that provide operating system support for a device.
IAD	Interface Association Descriptor. This is used to describe that two or more interfaces are associated to the same function. An ‘association’ includes two or more interfaces and all of their alternate setting interfaces.
Interface	An Entity representing a collection of zero or more endpoints that present functionality to a Host.
IT	Input Terminal.
OT	Output Terminal.
Payload Transfer	In the context of the USB Video Class, a Payload Transfer is a unit of data transfer common to bulk and isochronous endpoints. Each Payload Transfer includes a Payload Header followed by Payload Data. For isochronous endpoints, a Payload Transfer is contained in the data

	transmitted during a single (micro)frame: up to 1023 bytes for a full-speed endpoint; up to 1024 bytes for a high-speed endpoint; and up to 3072 bytes for a high-speed/high-bandwidth endpoint. For bulk endpoints, a Payload Transfer is contained in the data transmitted in a single bulk transfer (which may consist of multiple bulk data transactions).
Payload Data	Format-specific data contained in a Payload Transfer (excluding the Payload Header).
Payload Header	A header at the start of each Payload Transfer that provides data framing and encapsulation information.
PU	Processing Unit.
Request	A mechanism supported by the video function for the host software to interact with a Control within an Entity.
Sample Transfer	A sample transfer is composed of one or more payload transfer(s) representing a video sample.
STC	Source Time Clock. The clock used by the data source that governs the sampling of video (or related) data.
SU	Selector Unit.
TD	Terminal Descriptor.
Terminal	An Entity representing a source (Input Terminal) or sink (Output Terminal) for data flowing into or out of a video function.
UD	Unit Descriptor.
Unit	An Entity representing a transformation of data flowing through a video function.
USB	Universal Serial Bus.
USB Transaction	See USB 2.0 Chapter 5.
USB Transfer	See USB 2.0 Chapter 5.
VC	VideoControl; refers to the interface used for video function control.
VIC	Video Interface Collection; refers to the collection of VideoControl and VideoStreaming interfaces within the same video function.
VS	VideoStreaming; refers to the interface(s) used for video stream transport.
XU	Extension Unit.

2 Functional Characteristics

The video function is located at the interface level in the device class hierarchy. It consists of a number of interfaces grouping related pipes that together implement the interface to the video function.

Video functions are addressed through their video interfaces. Each video function has a single VideoControl (VC) interface and can have several VideoStreaming (VS) interfaces. The VideoControl (VC) interface is used to access the device controls of the function whereas the VideoStreaming (VS) interfaces are used to transport data streams into and out of the function. The collection of the single VideoControl interface and the VideoStreaming interfaces that belong to the same video function is called the Video Interface Collection (VIC). An Interface Association Descriptor (IAD) is used to describe the Video Interface Collection.

2.1 Video Interface Class

The Video Interface class groups all functions that can interact with USB-compliant video data streams. All functions that convert between analog and digital video domains can be part of this class. In addition, those functions that transform USB-compliant video data streams into other USB-compliant video data streams can be part of this class. Even analog video functions that are controlled through USB belong to this class.

In fact, for a video function to be part of this class, the only requirement is that it exposes one VideoControl Interface. No further interaction with the function is mandatory, although most functions in the video interface class will support one or more optional VideoStreaming interfaces for consuming or producing one or more video data streams.

The Video Interface class code is assigned by the USB. For details, see section A.1 "Video Interface Class Code".

2.2 Video Interface Subclass and Protocol

The Video Interface class is divided into subclasses that can be further qualified by the Interface Protocol code. The following three interface subclasses are defined in this specification.

- VideoControl Interface
- VideoStreaming Interface
- Video Interface Collection

The Interface Protocol is not used and must be set to 0x00.

The assigned codes can be found in sections A.2, "Video Interface Subclass Codes" and A.3, "Video Interface Protocol Codes" of this specification. All other subclass codes are unused and reserved except code 0xFF, which is reserved for vendor-specific extensions.

2.3 Video Function Topology

To be able to manipulate the physical properties of a video function, its functionality must be divided into addressable entities. The following two generic entities are identified:

- Units
- Terminals

Units provide the basic building blocks to fully describe most video functions. Video functions are built by connecting together several of these Units. A Unit has one or more Input Pins and a single Output Pin, where each Pin represents a cluster of logical data streams inside the video function. Units are wired together by connecting their I/O Pins according to the required topology. A single Output Pin can be connected to one or more Input Pins (fan-out allowed). However, a single Input Pin can only be connected to one Output Pin (fan-in disallowed). Loops or cycles within the graph topology are not allowed.

In addition, the concept of Terminal is introduced. There are two types of Terminals. An Input Terminal (IT) is an entity that represents a starting point for data streams inside the video function. An Output Terminal (OT) represents an ending point for data streams. From the video function's perspective, a USB endpoint is a typical example of an Input Terminal or Output Terminal. It either provides data streams to the video function (IT) or consumes data streams coming from the video function (OT). Likewise, a Charge Coupled Device (CCD) sensor, built into the video function is represented as an Input Terminal in the video function's model. Connection to a Terminal is made through its single Input Pin or Output Pin.

Input Pins of a Unit are numbered starting from one up to the total number of Input Pins on the Unit. The Output Pin number is always one. Terminals have one Input or Output Pin that is always numbered one.

The information traveling over I/O Pins is not necessarily of a digital nature. It is possible to use the Unit model to describe fully analog or even hybrid video functions. The mere fact that I/O Pins are connected together is a guarantee (by construction) that the protocol and format, used over these connections (analog or digital), is compatible on both ends.

Every Unit in the video function is fully described by its associated Unit Descriptor (UD). The Unit Descriptor contains all necessary fields to identify and describe the Unit. Likewise, there is a Terminal Descriptor (TD) for every Terminal in the video function. In addition, these descriptors provide all necessary information about the topology of the video function. They fully describe how Terminals and Units are interconnected.

The descriptors are further detailed in section 3, "Descriptors" of this document.

This specification describes the following types of standard Units and Terminals that are considered adequate to represent most video functions available today and in the near future:

- Input Terminal
- Output Terminal
- Selector Unit
- Processing Unit
- Extension Unit

Also, there are certain special Terminals that extend the functionality of the basic Input and Output Terminals. These special Terminals support additional Terminal Descriptor fields and Requests that are specific to the extended features these Terminals provide. These include:

- Media Transport Terminal (defined in *USB Device Class Definition for Video Media Transport Terminal* specification)
- Camera Terminal

The types of Units defined in this specification could be extended in future revisions, or via companion specifications. For example, a Tuner Unit could be added as a companion specification to accommodate devices with TV Tuners.

Inside a Unit or Terminal, functionality is further described through Video Controls. A Control typically provides access to a specific video property. Each Control has a set of attributes that can be manipulated or that present additional information about the behavior of the Control. Controls have attributes, which might include:

- Current setting
- Minimum setting
- Maximum setting
- Resolution
- Size
- Default

Consider a Brightness Control inside a Processing Unit. By issuing the appropriate requests, the Host software can obtain values for the Brightness Control's attributes and, for instance, use them to correctly display the Control in a User Interface. Setting the Brightness Control's *current setting* attribute allows the Host software to change the brightness of the video that is being streamed.

The ensemble of Unit Descriptors, Terminal Descriptors and Video Controls provide a full description of the video function to the Host. A generic class driver shall be able to fully control the video function. When functionality is represented by Extension Units, the class driver shall permit access to vendor-specific extensions via a pass-through mechanism. The implementation details of such a class driver are beyond the scope of this specification.

2.3.1 Input Terminal

The Input Terminal (IT) is used as an interface between the video function's "outside world" and other Units inside the video function. It serves as a receptacle for data flowing into the video function. Its function is to represent a source of incoming data after this data has been extracted from the data source. The data may include audio and metadata associated with a video stream. These physical streams are grouped into a cluster of logical streams, leaving the Input Terminal through a single Output Pin.

An Input Terminal can represent inputs to the video function other than USB OUT endpoints. A CCD sensor on a video camera or a composite video input is an example of such a non-USB input. However, if the video stream is entering the video function by means of a USB OUT endpoint, there is a one-to-one relationship between that endpoint and its associated Input Terminal. The class-specific Format descriptor contains a field that holds a direct reference to this Input Terminal. The Host needs to use both the endpoint descriptors and the Input Terminal descriptor to get a full understanding of the characteristics and capabilities of the Input Terminal. Stream-related parameters are stored in the endpoint descriptors. Control-related parameters are stored in the Terminal descriptor.

The symbol for the Input Terminal is depicted in the following figure.

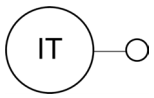

Figure 2-1 Input Terminal Icon

2.3.2 Output Terminal

The Output Terminal (OT) is used as an interface between Units inside the video function and the "outside world". It serves as an outlet for video information, flowing out of the video function. Its function is to represent a sink of outgoing data. The video data stream enters the Output Terminal through a single Input Pin.

An Output Terminal can represent outputs from the video function other than USB IN endpoints. A Liquid Crystal Display (LCD) screen built into a video device or a composite video out connector are examples of such an output. However, if the video stream is leaving the video function by means of a USB IN endpoint, there is a one-to-one relationship between that endpoint and its associated Output Terminal. The class-specific Format descriptor contains a field that holds a direct reference to this Output Terminal. The Host needs to use both the endpoint descriptors and the Output Terminal descriptor to fully understand the characteristics and capabilities of the Output Terminal. Stream-related parameters are stored in the endpoint descriptors. Control-related parameters are stored in the Terminal descriptor.

The symbol for the Output Terminal is depicted in the following figure.

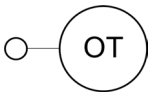

Figure 2-2 Output Terminal Icon

2.3.3 Camera Terminal

The Camera Terminal (CT) controls mechanical (or equivalent digital) features of the device component that transmits the video stream. As such, it is only applicable to video capture devices with controllable lens or sensor characteristics. A Camera Terminal is always represented as an Input Terminal with a single output pin. It provides support for the following features.

- Scanning Mode (Progressive or Interlaced)
- Auto-Exposure Mode
- Auto-Exposure Priority
- Exposure Time
- Focus
- Auto-Focus
- Iris
- Zoom
- Pan
- Roll
- Tilt

Support for any particular control is optional. The Focus control can optionally provide support for an auto setting (with an on/off state). If the auto setting is supported and set to the on state, the device will provide automatic focus adjustment, and read requests will reflect the automatically set value. Attempts to programmatically set the Focus control are ignored when in auto mode. When leaving Auto-Focus mode (entering manual focus mode), the control shall remain at the value that was in effect just before the transition.

2.3.4 Selector Unit

The Selector Unit (SU) selects from n input data streams and routes them unaltered to the single output stream. It represents a source selector, capable of selecting among a number of sources. It has an Input Pin for each source stream and a single Output Pin.

The symbol for the Selector Unit is depicted in the following figure.

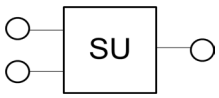

Figure 2-3 Selector Unit Icon (2 input pins)

2.3.5 Processing Unit

The Processing Unit (PU) controls image attributes of the video being streamed through it. It has a single input and output pin. It provides support for the following features:

User Controls

- Brightness
- Contrast
- Hue
- Saturation
- Sharpness
- Gamma
- Digital Multiplier (Zoom)

Auto Controls

- White Balance Temperature
- White Balance Component
- Backlight Compensation

Other

- Gain
- Power Line Frequency

Support for any particular control is optional. In particular, if the device supports the White Balance function, it shall implement either the White Balance Temperature control or the White Balance Component control, but not both. The User Controls indicate properties that are governed by user preference and not subject to any automatic adjustment by the device. The Auto Controls will provide support for an auto setting (with an on/off state). If the auto setting for a particular control is supported and set to the on state, the device will provide automatic adjustment of the control, and read requests to the related control will reflect the automatically set value. Attempts to programmatically set the related control are ignored when the control is in auto mode. When leaving an auto mode, the related control shall remain at the value that was in effect just before the transition.

The symbol for the Processing Unit is depicted in the following figure.

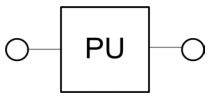

Figure 2-4 Processing Unit Icon

2.3.6 Extension Unit

The Extension Unit (XU) is the method provided by this specification to add vendor-specific building blocks to the specification. The Extension Unit can have one or more Input Pins and has a single Output Pin.

Although a generic host driver will not be able to determine what functionality is implemented in the Extension Unit, it shall report the presence of these extensions to vendor-provided client software, and provide a method for sending control requests from the client software to the Unit, and receiving status from the unit.

The symbol for the Extension Unit is depicted in the following figure.

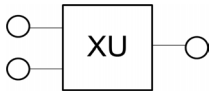

Figure 2-5 Extension Unit Icon

2.4 Operational Model

A device can support multiple configurations. Within each configuration can be multiple interfaces, each possibly having alternate settings. These interfaces can pertain to different functions that co-reside in the same composite device. Several independent video functions can exist in the same device. Interfaces that belong to the same video function are grouped into a Video Interface Collection described by an Interface Association Descriptor. If the device contains multiple independent video functions, there must be multiple Video Interface Collections (and hence multiple Interface Association Descriptors), each providing full access to their associated video function.

As an example of a composite device, consider a desktop camera equipped with a built in microphone. Such a device could be configured to have one interface collection dealing with configuration and control of the audio function, while another interface collection deals with its video aspects. One of those, the VideoControl interface, is used to control the inner workings of the function, whereas the other, the VideoStreaming interface, handles the data traffic received from the camera video subsystem.

Video Interface Collections can be dynamic in devices that support multiple operating modes. Because the VideoControl interface, together with its associated VideoStreaming interface(s), constitutes the ‘logical interface’ to the video function, they must all come into existence at the same moment in time. Changing the operating mode of a device causes the previous Video Interface Collection to be replaced with a new Video Interface Collection, followed by re-initialization of the host software. This specification does not provide a mechanism for the host to initiate such a mode change, which is typically initiated via a physical switch on the device.

As stated earlier, video functionality is located at the interface level in the device class hierarchy. The following sections describe the Video Interface Collection, containing a single VideoControl interface and optional VideoStreaming interfaces, together with their associated endpoints that are used for video function control and for data stream transfer.

2.4.1 Video Interface Collection

A device must use an Interface Association Descriptor to describe a Video Interface Collection for each device function that requires a VideoControl Interface and one or more VideoStreaming interfaces. The Interface Association Descriptor must always be returned as part of the device's complete configuration descriptor in response to a GetDescriptor(Configuration) request. The Interface Association Descriptor must be located before the VideoControl Interface and its associated VideoStreaming Interfaces (including all alternate settings). All of the interface numbers in the set of associated interfaces must be contiguous.

2.4.2 VideoControl Interface

To control the functional behavior of a particular video function, the Host can manipulate the Units and Terminals inside the video function. To make these objects accessible, the video function must expose a single VideoControl interface. This interface can contain the following endpoints.

- A control endpoint for manipulating Unit and Terminal settings and retrieving the state of the video function. This endpoint is mandatory, and the default endpoint 0 is used for this purpose.
- An interrupt endpoint for status returns. This endpoint is optional, but may be mandatory under certain conditions. See section 2.4.2.2, "Status Interrupt Endpoint" for further information.

The VideoControl interface is the single entry point to access the internals of the video function. All requests that are concerned with the manipulation of certain Video Controls within the video function's Units or Terminals must be directed to the VideoControl interface of the video function. Likewise, all descriptors related to the internals of the video function are part of the class-specific VideoControl interface descriptor.

This specification defines a single alternate setting for the VideoControl interface, the default alternate setting zero.

2.4.2.1 Control Endpoint

The video interface class uses endpoint 0 (the default pipe) as the standard way to control the video function using class-specific requests. These requests are always directed to one of the Units or Terminals that make up the video function. The format and contents of these requests are detailed further in this document.

2.4.2.2 Status Interrupt Endpoint

A USB VideoControl interface can support an optional interrupt endpoint to inform the Host about the status of the different addressable entities (Terminals, Units, interfaces and endpoints) inside the video function. The interrupt endpoint, if present, is used by the entire Video Interface Collection to convey status information to the Host. It is considered part of the VideoControl interface because this is the anchor interface for the Collection.

This interrupt endpoint is mandatory if:

- The device supports hardware triggers for still image capture (see section 2.4.2.3, "Hardware Trigger Interrupts").
- The device implements any *AutoUpdate controls* (controls supporting device initiated changes).
- The device implements any *Asynchronous controls* (see section 2.4.4, "Control Transfer and Request Processing").

The interrupt packet is a variable size data structure depending on the originator of the interrupt status. The **bStatusType** and **bOriginator** fields contain information about the originator of the interrupt. The **bEvent** field contains information about the event triggering the interrupt. If the originator is the Video Control interface, the **bSelector** field reports the Control Selector of the control that issued the interrupt. Any addressable entity inside a video function can be the originator.

The contents of the **bOriginator** field must be interpreted according to the code in D3..0 of the **bStatusType** field. If the originator is the VideoControl interface, the **bOriginator** field contains the Terminal ID or Unit ID of the entity that caused the interrupt to occur. If the **bOriginator** field is set to zero, the *virtual* entity interface is the originator. This can be used to report global VideoControl interface changes to the Host. If the originator is a VideoStreaming interface, the **bOriginator** field contains the interface number of the VideoStreaming interface. This scheme is unambiguous because Units and Terminals are not allowed to have an ID of zero.

If the originator is the VideoControl interface, the **bAttribute** field indicates the type of Control change.

The contents of the **bEvent** field must also be interpreted according to the code in D3..0 of the **bStatusType** field. If the originator is the VideoStreaming interface, there are additional button press events defined as described in the table below.

For all originators, there is a Control Change event defined. Controls that support this event will trigger an interrupt when a host-initiated or externally-initiated control change occurs. The interrupt shall only be sent when the operation corresponding to the control change is completed by the device.

A Control shall support Control Change events if any of the following is true:

- The Control state can be changed independently of host control.

- The Control can take longer than 10ms from the start of the Data stage through the completion of the Status stage when transferring to the device (SET_CUR operations).

If a control is required to support Control Change events, the event shall be sent for all SET_CUR operations, even if the operation can be completed within the 10ms limit. The device indicates support for the Control Change event for any particular control via the GET_INFO attribute (see section 4.1.2, "Get Request"). Section 2.4.4, "Control Transfer and Request Processing" describes in detail the interaction of Control Transfers (Requests) and Control Change events.

The following tables specify the format of the status packet.

Table 2-1 Status Packet Format

Offset	Field	Size	Value	Description
0	**bStatusType**	1	Bitmap/Number	D7..4: Reserved D3..0: Originator 0 = Reserved 1 = VideoControl interface 2 = VideoStreaming interface
1	**bOriginator**	1	Number	ID of the Terminal, Unit or Interface that reports the interrupt

When the originator is a Video Control Interface, the rest of structure is:

Table 2-2 Status Packet Format (VideoControl Interface as the Originator)

Offset	Field	Size	Value	Description
2	**bEvent**	1	Number	0x00: Control Change 0x01 – 0xFF: Reserved
3	**bSelector**	1	Number	Control Change Report the Control Selector of the control that issued the interrupt.
4	**bAttribute**	1	Number	Specify the type of control change: 0x00: Control value change 0x01: Control info change 0x02: Control failure change 0x03 – 0xFF: Reserved

5	**bValue**	n		See control request description in section 4.2 "VideoControl Requests". **bAttribute:** **Description:** 0x00 Equivalent to the result of a GET_CUR request 0x01 Equivalent to the result of a GET_INFO request 0x02 Equivalent to the result of a GET_CUR request on VC_REQUEST_ERROR_ CODE_CONTROL

When the originator is a Video Streaming Interface the rest of the structure is:

Table 2-3 Status Packet Format (VideoStreaming Interface as the Originator)

Offset	Field	Size	Value	Description
2	**bEvent**	1	Number	All originators: 0x00 = Button Press 0x01 – 0xFF = Stream Error
3	**bValue**	n	Number	Button Press: (n=1) 0x00: Button released 0x01: Button pressed

2.4.2.3 Hardware Trigger Interrupts

One of the defined usages of the Status Interrupt Endpoint is for hardware triggers to notify host software to initiate still image capture. When the hardware detects a button press, for example, the Status Interrupt Endpoint will issue an interrupt originating from the relevant VideoStreaming interface. The event triggering the interrupt (button press or release) is indicated in the interrupt packet. The default, initial state of the button is the "*release*" state.

The device will have to specify whether it supports hardware triggers, and how the Host software should respond to hardware trigger events. These are specified in the class-specific descriptors within the relevant VideoStreaming interface. See section 3, "Descriptors".

2.4.2.4 Still Image Capture

A common feature of video cameras is the support of still image capture associated with a video stream. This can be initiated either by programmatic software triggers or hardware triggers.

Depending on the method used, the still image frame may have to be the same size as the video frames that are being streamed. There are several supported methods of capturing the still image, and the device will have to specify which method it supports in the class-specific descriptors within the relevant VideoStreaming interface.

Method 1 - The host software will extract the next available video frame from the active video pipe in the relevant VideoStreaming interface upon receiving the hardware trigger event. The hardware does not interrupt or alter the video stream in this case. For this method, the still image frame is always the same size as the video frames being streamed.

Method 2 – If the device supports higher-quality still images, it has the option of streaming still-image-specific packets across the active video pipe. In this case, the host software will temporarily suspend video streaming, select the maximum bandwidth alternate setting (subject to bandwidth availability), send a VS_STILL_IMAGE_TRIGGER_CONTROL Set request with the "Transmit still image" option (see section 4.3.1.4, "Still Image Trigger Control"), and prepare to receive the still image data. The device transmits the still image data marked as such in the payload header (see section 2.4.3.2.2, "Sample Isochronous Transfers"). Once the complete still image is received, the host software will then revert back to the original alternate setting, and resume video streaming.

Method 3 – This method enables the capture of higher-quality still images from a dedicated bulk still image pipe. By doing so, the active streams would continue uninterrupted. There are two cases covered by this method.

In the first case, the host software initiates the still image capture from the device. It does so by issuing a VS_STILL_IMAGE_TRIGGER_CONTROL *Set* request with the "Transmit still image via dedicated bulk pipe" option (see section 4.3.1.4, "Still Image Trigger Control"). In this case, after issuing the request, the host will start receiving the still image from the bulk still image endpoint of the relevant VideoStreaming interface. The device captures the high-quality still image and transmits the data to the bulk still image endpoint. While transmission is occurring, the **bTrigger** field of the VS_STILL_IMAGE_TRIGGER_CONTROL control shall remain as "Transmit still image via dedicated bulk pipe". After transmission is complete, the device shall reset the control to "Normal operation" and trigger a control change interrupt via the Status Interrupt endpoint.

In the second case, the device initiates the still image transmission after detecting a hardware trigger. When the hardware detects a button press, the Status Interrupt endpoint will issue an interrupt originating from the relevant VideoStreaming interface. If the **bTriggerUsage** field of the selected format descriptor is set as initiating still image capture, the device shall set the **bTrigger** field of the VS_STILL_IMAGE_TRIGGER_CONTROL control to “Transmit still image via dedicated bulk pipe”. The Host software should then begin receiving still image data that was captured by the device after it received the interrupt. After transmission is complete, the device shall reset the **bTrigger** field to “Normal operation”. The host software can abort data transmission by issuing a VS_STILL_IMAGE_TRIGGER_CONTROL request with the “Abort

still image transmission" option. In either case, the device shall trigger a control change interrupt via the Status Interrupt endpoint

The following table summarizes endpoint usage for the various methods of still image capture.

Table 2-4 Summary of Still Image Capture Methods

	Isochronous video data pipe	Bulk video data pipe
Method 1	1 Isochronous (Video)	1 Bulk (Video)
Method 2	1 Isochronous (Video/Still)	1 Bulk (Video/Still)
Method 3	1 Isochronous (Video) 1 Bulk (Still)	1 Bulk (Video) 1 Bulk (Still)

2.4.2.5 Optical and Digital Zoom

Optical and digital zoom are functionally independent, so each will be discussed separately in the following sections. Although functionally independent, users will expect a single zoom control that integrates both.

2.4.2.5.1 Optical Zoom

Although lens groups can be quite sophisticated, this specification describes a simple two-lens system, which is sufficient to model optical zoom. Given objective and ocular lens focal lengths ($L_{objective}$ and L_{ocular}), magnification (M) can be calculated as follows:

$$M = \frac{L_{objective}}{L_{ocular}}$$

The objective lens is the one nearest the subject, while the ocular lens is the one nearest the viewer, or in our case, the camera sensor. A zoom lens varies the objective focal length.

Since magnification is a ratio of the objective and ocular focal lengths, the Units used to specify these focal lengths can be of any resolution supported by the device. In other words, these Units do not need to be specified in real physical units (millimeters or fractions of inches). The only requirement is that the two focal lengths are specified in the same units.

Note that when $L_{objective} < L_{ocular}$, the lenses are at a wide-angle setting. The subject will appear smaller than life, and the field of view will be wider.

L_{ocular} will be a device-specific constant value for each camera implementation, so it will be specified within the static Camera Terminal descriptor. If a camera implements an optical zoom function, $L_{objective}$ can vary within a specified range. In order to properly represent the range of

magnification, $L_{objective}$ will be specified as a range L_{min} to L_{max}, which will also be specified within the static Camera Descriptor.

Finally, the variable position within the range of possible $L_{objective}$ values will be specified via a dynamic Camera Zoom Control, as integral values Z_{min}, Z_{max}, Z_{step}, and Z_{cur}. See sections 4.2.2.1.11, "Zoom (Absolute) Control" and 4.2.2.1.12, "Zoom (Relative) Control". This allows the Units of the objective lens focal length to be de-coupled from the Units used to control zoom. For simplicity, Z_{step} will be constrained to equal one (1). Values of L_{min} and L_{max} are constrained to be non-zero integral numbers; however, for the purpose of the following calculations, L_{cur} will be a real number.

Note: A typical choice for L_{ocular} would be half the length of a diagonal line of the imager (CCD, etc.), however there is no requirement for this value to be a direct physical measurement.

Given a known Z_{cur}, the current objective focal length (L_{cur}) can be calculated as follows:

$$L_{cur} = \frac{(Z_{cur} - Z_{min}) * (L_{max} - L_{min})}{(Z_{max} - Z_{min})} + L_{min}$$

From this, the relative magnification can be calculated as follows:

$$M = \frac{L_{cur}}{L_{ocular}}$$

Working from the opposite direction, given a known magnification (M), L_{cur} can be calculated as follows:

$$L_{cur} = M * L_{ocular}$$

From this, the current Zoom control value (Z_{cur}) can be calculated as follows:

$$Z_{cur} = \left\lfloor \frac{(L_{cur} - L_{min}) * (Z_{max} - Z_{min})}{(L_{max} - L_{min})} \right\rfloor + Z_{min}$$

To further simplify the calculations, Z_{min} can be constrained to be zero (0). The camera designer will choose the values and ranges of the remaining variables according to the capabilities of the device.

As an example, substituting some plausible values for each of these variables:

$L_{min} = 800$
$L_{max} = 10000$
$Z_{min} = 0$
$Z_{max} = 255$

The current Objective focal length (L_{cur}) can be calculated as follows:

$$L_{cur} = \frac{Z_{cur} * 9200}{255} + 800$$

The current Zoom control value (Z_{cur}) can be calculated as follows:

$$Z_{cur} = \left\lfloor \frac{(L_{cur} - 800) * 255}{9200} \right\rfloor$$

When choosing a camera sensor to match a lens system, the camera designer may need to consider a *multiplier* effect caused by a sensor that is smaller than the exit pupil of the ocular lens. This multiplier will not be represented explicitly in the USB Video Class specification, since its effect can be represented via adjustments to the $L_{objective}$ values.

Note The Z_{cur} value can be mapped to the physical lens position sensor control/status register.

2.4.2.5.2 Digital Zoom

Digital zoom is applied after the image has been captured from the sensor. Thus, digital zoom is independent of optical zoom, and is a function of either the Processing Unit or host post-processing. Although digital zoom is independent of optical zoom, users have come to expect that camera implementations will not apply digital zoom until full optical zoom has been realized. This will be enforced by the host software. There is no requirement for the device to enforce this, but it is recommended.

Digital zoom is represented as a *multiplier* of the current optical magnification of the captured image. In order to change the amount of digital zoom, the multiplier is changed through a range from 1 to some maximum value m_{max}, and m_{max} will be specified in the Processing Unit Descriptor. The position within the range of possible values of multiplier *m* will be expressed via a Processing Unit Digital Multiplier Control, as Z'_{min}, Z'_{max}, Z'_{step}, and Z'_{cur}. See section

4.2.2.3.15, "Digital Multiplier Control". This allows the multiplier resolution to be described by the device implementation. Z'_{step} will be constrained to equal one (1).

Given a known Z'_{cur}, the current multiplier m_{cur} can be calculated as follows:

$$m_{cur} = \frac{(Z'_{cur} - Z'_{min}) * (m_{max} - 1)}{(Z'_{max} - Z'_{min})} + 1$$

From this, and referring to the optical zoom values of L_{max} and L_{ocular} described in the previous section, the total magnification M' can be calculated as follows:

$$M' = \frac{L_{max}}{L_{ocular}} * m_{cur}$$

Working from the opposite direction, given a known magnification M, the multiplier m_{cur} can be calculated as follows:

$$m_{cur} = M' * \frac{L_{ocular}}{L_{max}}$$

From this, the current Digital Multiplier Control value (Z'_{cur}) can be calculated as follows:

$$Z'_{cur} = \left\lfloor \frac{(m_{cur} - 1) * (Z'_{max} - Z'_{min})}{(m_{max} - 1)} \right\rfloor + Z'_{min}$$

For simplicity, Z'_{min} can be constrained to be zero (0). The camera designer will choose the values and ranges of the remaining variables according to the capabilities of the device.

As an example, substituting some plausible values for each of these variables:

$m_{max} = 40$
$Z'_{min} = 0$
$Z'_{max} = 255$

The current multiplier (m_{cur}) can be calculated as follows:

$$m_{cur} = \frac{Z'_{cur} * 39}{255} + 1$$

The current Digital Zoom control value (Z'_{cur}) can be calculated as follows:

$$Z'_{cur} = \left\lfloor \frac{(m_{cur} - 1) * 255}{39} \right\rfloor$$

In addition to the Digital Multiplier Control, devices may optionally support a Digital Multiplier Limit control, allowing either the camera or the host to establish a temporary upper limit for the Z'_{cur} value. This control may be read-only if the limit can only be established via physical camera configuration. If this control is used to decrease the limit below the current Z'_{cur} value, the Z'_{cur} value will be adjusted to match the new limit.

2.4.2.5.3 Relationship between Optical and Digital Zoom

As mentioned in the preceding sections, users expect to use a single control on the device (or from within an application on the host) to traverse the entire range of optical and digital zoom. Further, users expect that digital zoom will not be active except at full optical zoom.

The following diagram illustrates the relationship between optical and digital zoom, and the constraints on the zoom control variables:

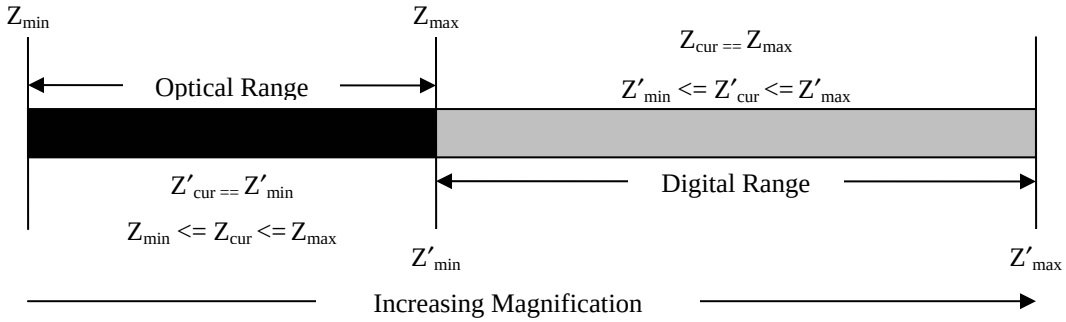

Figure 2-6 Relationship between Optical and Digital Zoom

2.4.2.5.4 Absolute vs. Relative Zoom

The equations and examples given in the previous sections describe independent, *absolute* optical and digital zoom controls. However, based on users' expectations that devices provide a single relative zoom control allowing them to move across the entire zoom range (from wide to telephoto and back again), many cameras will implement a *relative* zoom control that supports increasing and decreasing the zoom parameters without actually specifying the parameter values. Devices that allow only *relative* zoom control should still report the optical focal lengths and maximum digital multiplier in their respective descriptors, as well as maintain read-only *absolute* optical and digital zoom controls. This way, the host software will always be able to determine the current state of the zoom values.

2.4.3 VideoStreaming Interface

VideoStreaming interfaces are used to interchange digital data streams between the Host and the video function. They are optional. A video function can have zero or more VideoStreaming interfaces associated with it, each possibly carrying data of a different nature and format. Each VideoStreaming interface can have one isochronous or bulk data endpoint for video, and an optional dedicated bulk endpoint for still images related to the video (only for method 3 of still image transfer. See section 2.4.2.4 "Still Image Capture"). This construction guarantees a one-to-one relationship between the VideoStreaming interface and the single data stream related to the endpoint.

A VideoStreaming interface with isochronous endpoints must have alternate settings that can be used to change certain characteristics of the interface and underlying endpoint(s). A typical use of alternate settings is to provide a way to change the bandwidth requirements an active isochronous pipe imposes on the USB. All devices that transfer isochronous video data must incorporate a zero-bandwidth alternate setting for each VideoStreaming interface that has an isochronous video endpoint, and it must be the default alternate setting (alternate setting zero). A device offers to the Host software the option to temporarily relinquish USB bandwidth by switching to this alternate setting. The zero-bandwidth alternate setting does not contain a VideoStreaming isochronous data endpoint descriptor.

A VideoStreaming interface containing a bulk endpoint for streaming shall support only alternate setting zero. Additional alternate settings containing bulk endpoints are not permitted in a device that is compliant with the Video Class specification. This restriction does not prohibit the mix of bulk and isochronous endpoints when the bulk endpoints are used solely for Still Image Transfer Method 3. In that case, each alternate setting will include the descriptors for both an isochronous endpoint and a bulk endpoint.

If a VideoStreaming interface with an isochronous endpoint supports a set of video parameter combinations (including video format, frame size and frame rate) that utilize significantly varying amounts of bandwidth across all combinations, it is recommended that the VideoStreaming interface support a range (greater than two) of alternate interface settings with varying maximum packet sizes. By doing so, the host would be able to select an appropriate

alternate setting for the given video parameter combination that provides for minimum wastage of bus bandwidth, if any.

For device implementers, the process of determining the number of alternate settings to be provided and the maximum packet size for the video data endpoint in each alternate setting is implementation dependent, and would depend on the bandwidth usage across the range of video parameter combinations that the VideoStreaming interface is capable of supporting.

2.4.3.1 Stream Bandwidth Selection

The bandwidth required by a video stream can be satisfied by a USB bandwidth that is equal to or greater than the function stream bandwidth. This can be illustrated as follows.

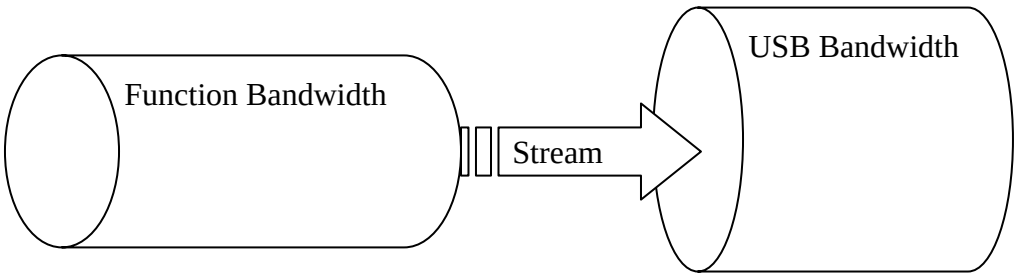

Figure 2-7 Stream Bandwidth Selection

The optimal allocation of the USB bandwidth to match the function's bandwidth requirement is achieved via negotiation between the host and the device.

The negotiation process allows the host to provide preferred stream parameters to the device, while the device selects the best combination of streaming parameters and recommends the optimal alternate interface for the host to perform bandwidth allocation. The host is free to choose a different alternate interface than was recommended by the device since the recommended bandwidth may not be available. The device is responsible for choosing the live streaming parameters once the bandwidth is allocated. These parameters may be different than originally agreed upon during the negotiation process. However, during the negotiation process, the host provided hints to the device indicating the preferred way to choose the live stream parameters.

Once bandwidth has been allocated and streaming started, further parameter negotiation between the host and the device can be performed without disturbing the current stream. Streaming parameters are set as a group so that the function will have all information available while it attempts to determine a working set or recommend an alternate interface.

See section 4.3.1.1, "Video Probe and Commit Control" for a complete description of the negotiation process.

Still image transfer uses a similar mechanism.

2.4.3.2 Video and Still Image Samples

A video (or still image) sample refers to an encoded block of video data that the format-specific decoder is able to accept and interpret in a single transmission. A single video sample may or may not correspond to a single decoded video frame, depending on the video format in use. For example, a YUV video stream (which has no inter-frame compression) would have a one to one correspondence between a video sample and video frame. However, a MPEG2-TS data stream will require many video samples (or TS packets) to form a decoded video frame.

A single video sample may require multiple Payload Transfers. Conversely, there may be one or more video samples within a single Payload Transfer. In the latter case, there must be an integral number of fixed size samples within each Payload Transfer.

The VideoStreaming endpoint(s) encapsulate data with the class-defined payload header. This encapsulation is identical for payload transfers on both isochronous and bulk endpoint types, and applies to both the streaming and still image endpoints.

The following block diagram details the protocol layering and abstraction used in payload transfers.

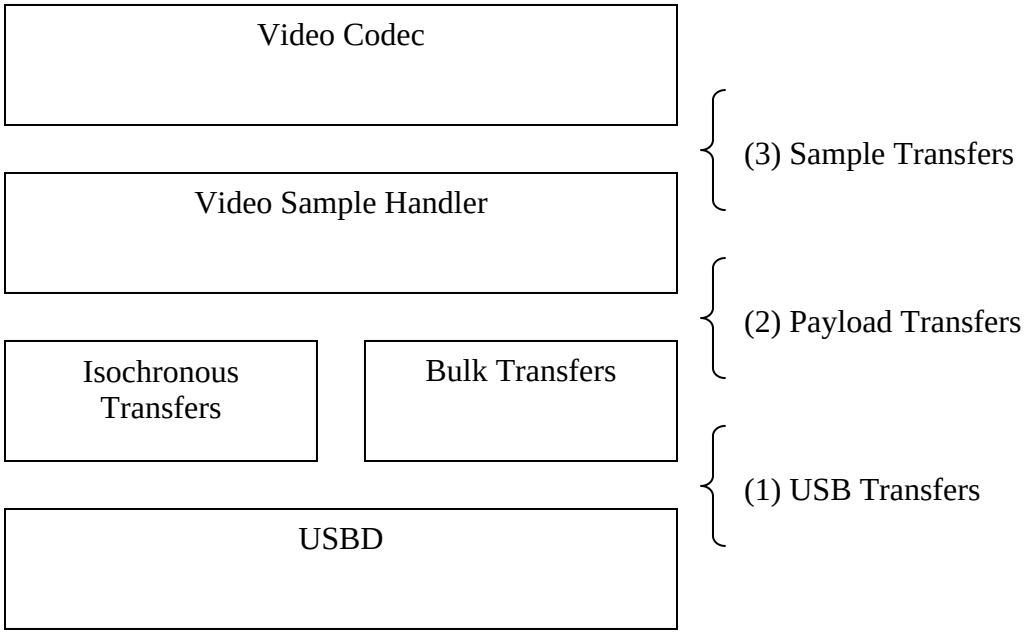

Figure 2-8 Protocol Layering and Abstraction

1. I/O Request Packet (IRP) requests from the client to the USB system software result in USB transfers.
2. In response to IRP completion, the host software forwards the data in the form of payload transfers. The bulk and isochronous handlers hide the transfer type differences from the upper layers of the protocol stack.
3. The video sample handler accumulates the individual payload transfers to form a sample transfer.

A payload transfer is composed of the class-defined payload header (see section 2.4.3.3 "

Video and Still Image Payload Headers") followed by the format-specific payload data.

Figure 2-9 A Payload Transfer

2.4.3.2.1 Sample Bulk Transfers

The following examples show the relationship between Video Samples, Payload Transfers and the token and data packets when exchanging bulk transfers with a device. Handshake packets are not shown for the sake of clarity.

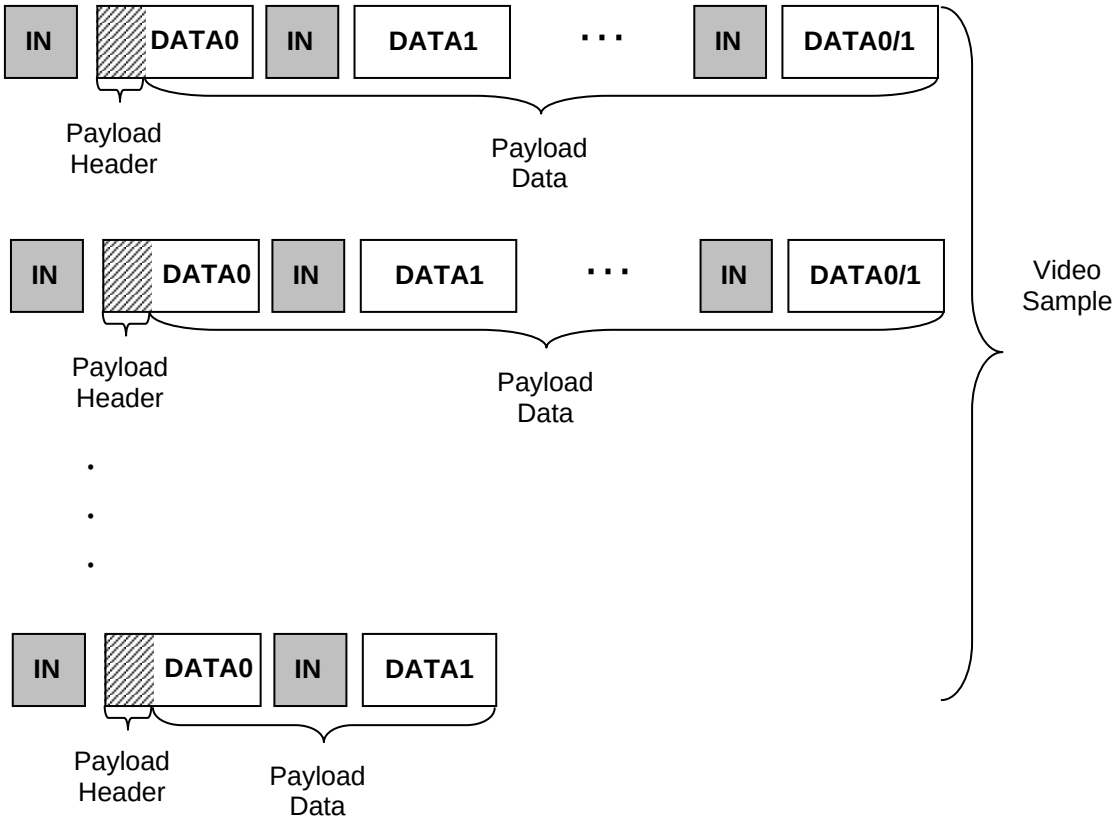

Figure 2-10 Sample Bulk Read (Multiple Transfers per Sample)

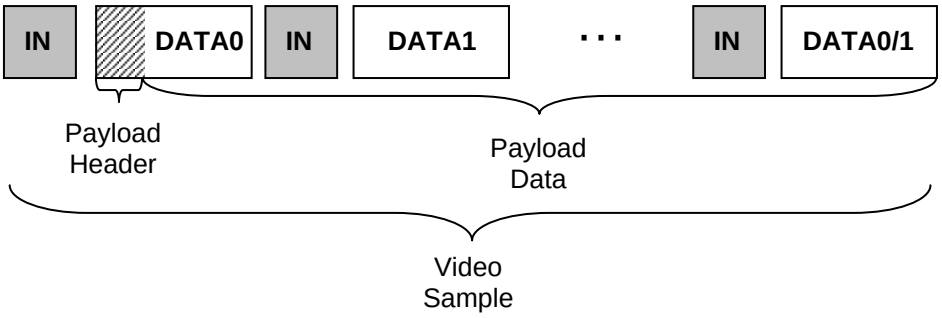

Figure 2-11 Sample Bulk Read (Single Transfer per Sample)

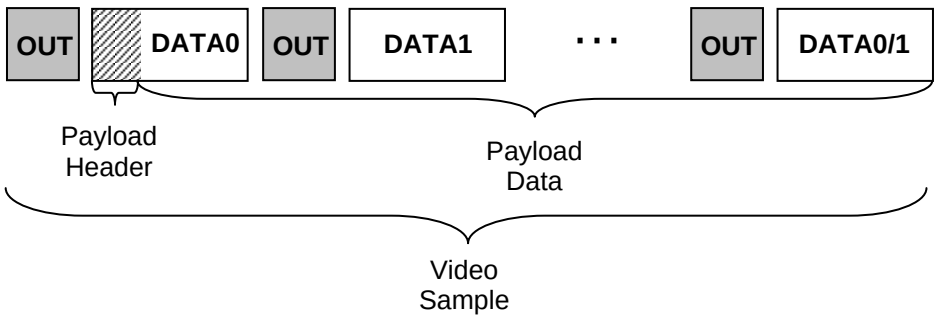

Figure 2-12 Sample Bulk Write (Single Transfer per Sample)

2.4.3.2.2 Sample Isochronous Transfers

The following examples show the relationship between Video Samples, Payload Transfers and the token and data packets when exchanging isochronous transfers with a device. The actual video sample size and bandwidth usage (i.e. number of data transactions and amount of data in the last transaction of each payload) will vary according to the requirements of the device and payload.

Figure 2-13 gives an example of a High Speed/High Bandwidth transfer over an IN endpoint.

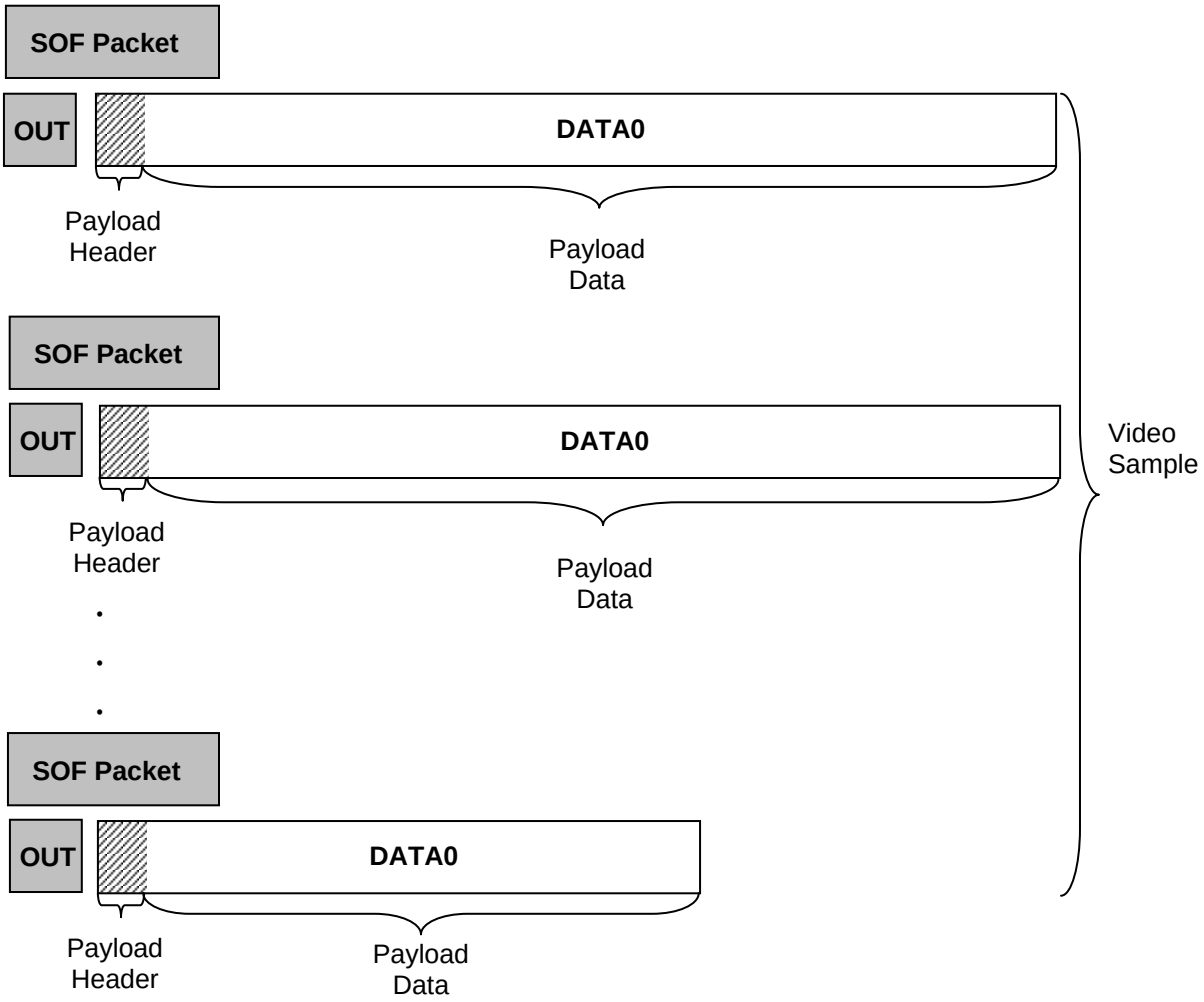

Figure 2-16 Sample Isochronous Transfer, OUT endpoint

2.4.3.3 Video and Still Image Payload Headers

Every payload transfer containing video or still-image sample data must start with a payload header.

The format of the payload header is defined as follows.

Table 2-5 Format of the Payload Header

Offset	Field	Size	Value	Description
0	**bHeaderLength**	1	Number	Length of the payload header in bytes including this field.
1	**bmHeaderInfo**	1	Bitmap	Provides information on the sample data following the header, as well as the availability of optional header fields in this header. D0: Frame ID – This bit toggles between 0 and 1 every time a new video frame begins. D1: End of Frame – This bit is set if the following payload data marks the end of the current video or still image frame. D2: Presentation Time – This bit is set if the **dwPresentationTime** field is being sent as part of the header. D3: Source Clock Reference – This bit is set if the **dwSourceClock** field is being sent as part of the header. D4: Reserved D5: Still Image – This bit is set if the following data is part of a still image frame, and is only used for methods 2 and 3 of still image capture. D6: Error – This bit is set if there was an error in the video or still image transmission for this payload. The Stream Error Code control would reflect the cause of the error. D7: End of header – This bit is set if this is the last header group in the packet, where the header group refers to this field and any

				optional fields identified by the bits in this field (Defined for future extension).

The following fields may or may not be included in the header, depending on the bits that were specified in the **bmHeaderInfo** field above.

These fields are in the order in which they are specified in the bitmap header field above, in the order of least significant bit first. Because the header itself might be extended in the future, the offset of **dwPresentationTime** is also variable. The device will indicate if it supports these fields in the Payload Format Descriptor within the class-specific VideoStreaming descriptor. See section 3.9.2.3 "Payload Format Descriptors".

Table 2-6 Extended Fields of the Payload Header

Offset	Field	Size	Value	Description
Variable	**dwPresentationTime**	4	Number	The source clock time in native device clock units when the raw frame capture begins. This field may be repeated for multiple payload transfers comprising a single video frame, with the restriction that the value remains the same throughout that video frame.
Variable	**scrSourceClock**	6	Number	A two-part Source Clock Reference (SCR) value D31..D0: Source Time Clock in native device clock units D42..D32: 1KHz SOF token counter D47..D43: Reserved, set to zero. The least-significant 32 bits (D31..D0) contain clock values sampled from the System Time Clock (STC) at the source. This clock may be of any resolution. If the source is the USB device, the resolution is at the discretion of the device implementer; if the source is the host, the resolution is based on the highest resolution clock available to the host. The times at which the STC is sampled must be correlated with the USB Bus Clock. To that end, the next most-significant 11 bits of the SCR (D42..D32) contain a 1 KHz SOF counter,

				representing the frame number at the time the STC was sampled. The STC is sampled at arbitrary SOF boundaries. The SOF counter is the same size and frequency as the frame number associated with USB SOF tokens; however it is not required to match the current frame number. This allows implementations using a chipset that can trigger on SOF tokens (but not accurately obtain the Frame number) to keep their own frame counters. The most-significant 5 bits (D47..D43) are reserved, and must be set to zero. The maximum interval between SCR values is 100ms, or the video frame interval, whichever is greater. Shorter intervals are permitted.

The periodic transmission of the **dwPresentationTime** and **dwSourceClock** fields is mandatory if all of the following conditions are true.

- The device has multiple video and/or audio source functions and is sending audio and video streams to the host.
- The video and/or audio streams are interrelated and therefore need to be kept synchronized.
- The stream format in use does not already contain timestamp and clock reference information (MPEG2-TS is an example of a format that contains this information).
- The sample is part of a video frame (and not a still image frame).

These time information fields allow the host software to reconstruct the source clock to support high-quality synchronization between separate data pipes (audio, video, etc.) and rate matching between the data source and sink, as discussed in the following section.

2.4.3.4 Stream Synchronization and Rate Matching

To properly synchronize multiple audio and video streams from a media source, the media source must provide (to the media sink) its local stream latency, periodic clock reference information, and a way for the media sink to determine the proper presentation time for samples from each stream (relative to the other streams).

2.4.3.4.1 Latency

The media source is required to report its internal latency (delay from data acquisition to data delivery on the bus). This latency reflects the lag introduced by any buffering, compression, decompression, or processing done by the stream source. Without latency information for each stream, a media sink (or rendering device) cannot properly correlate the presentation times of each stream.

In the case of a video source, this means that the source must guarantee that the portion of a sample fully acquired as of SOF_n (Start Of Frame n) will have been completely sent to the bus as of SO$F_{n+}\delta$. Latency δ is the source's internal delay expressed in frames. For high-speed endpoints, the resolution increases to 125 microseconds, and the delay will be specified in micro-frames. Since SOF is only seen once per frame, the micro-frames must be counted. Every VideoStreaming interface must report this latency value. See the description of the **wDelay** parameter in section 4.3.1.1, "Video Probe and Commit Controls". By following these rules, phase jitter is limited to ±1 millisecond (or ±125 microseconds for high-speed endpoints). It is up to the video sink to synchronize streams by scheduling the rendering of samples at the correct moment, taking into account the internal delays of all media streams being rendered.

2.4.3.4.2 Clock Reference

Clock reference information is used by a media sink to perform clock rate matching. Rate matching refers to the synchronization of the media sink's rendering clock with the media source's sampling clock. Without clock rate matching, a stream will encounter buffer overrun or underrun errors. This has not been a problem with audio streams due to the relative ease of performing audio sample rate conversion. However, sample rate conversion is significantly more difficult with video, so a method for rate matching is required.

To understand the problem of clocks running at slightly different rates, consider the following example. For simplicity, assume that video buffers can be filled instantaneously, and that there is one buffer available to be filled at any given time within the video frame interval. Also assume that the two crystals governing the source and rendering clocks operate with 100ppm (parts per million) accuracy. The accuracy value is a ratio that can be applied such that for every frame, the clock will drift by a fraction of the frame that is equal to the ratio. In other words, two clocks with accuracy of 100ppm could have a worst case drift relative to each other of 1/5,000th of a frame (two clocks at opposite extremes of their valid operating range for a cumulative error ratio of 2 * 100/1,000,000). Therefore, a frame glitch will occur once every 5,000 frames. At a frame rate of 30 fps, this would equate to a glitch every 166.67 seconds. At a frame rate of 60 fps, it's worse, with one glitch every 83.3 seconds.

Frame glitches can be postponed, but not avoided, by adding additional buffers to hold video frames before they are rendered. If the source clock is running slower than the rendering clock,

the buffer underrun could only be postponed by letting the extra buffers fill to a certain threshold before rendering, resulting in unacceptable latency. Once the first glitch occurs, the extra buffers are effectively useless, since the behavior will degrade to the single-buffer case from that point onward.

This specification assumes that in all cases, the media sink has no control over the media source clock, and that the source and sink do not "slave" to a common clock (the bus clock lacking sufficient resolution). Also, due to cost constraints, additional isochronous endpoints to communicate clock rate information will not be used. Therefore, this specification requires that a video stream include clock reference information that can be used to adjust the rendering clock rate. The clock reference information may be encapsulated in a transport stream, or it may be provided via an optional field in each payload header. This field becomes required in the latter case.

2.4.3.4.3 Presentation Time

For fixed rate streams, the presentation time can be derived from the data stream. For a fixed-rate audio stream (e.g., PCM), the media sink can derive the presentation time from the stream offset (typically the count of bytes since start of capture). For variable rate streams, each sample must be accompanied by a presentation timestamp. The media sink is responsible for converting the timestamp to native units and adjusting the timestamp to account for the local clock offset when a stream starts, as well as accounting for source stream latency. Even though video streams might arrive at the media sink at a fixed frame rate, if they are subject to variable rate compression and encoding, they are not considered fixed-rate streams and will require timestamps on the samples.

2.4.3.5 Dynamic Frame Interval Support

In order to adjust to different environmental conditions, such as varying lighting conditions, it may be necessary for a video device (such as a camera) to dynamically change the frame interval and sensor exposure time to maintain acceptable image quality while streaming.

After bus bandwidth for the video data pipe of the corresponding VideoStreaming interface has been allocated and streaming has commenced, the data source may dynamically vary the frame interval (and the corresponding frame rate), as long as the new frame interval does not require greater bus bandwidth than what was originally allocated. The data sink would determine the new frame interval based on the Presentation Time Stamp (PTS) information included in the video payload headers.

2.4.3.6 Dynamic Format Change Support

Certain devices, such as those that contain a tape media transport, are capable of dynamically changing the video format being streamed to the host while streaming is occurring. Since the

new video format may have different bus bandwidth requirements from the old format, the host must be notified of the format change and be allowed to perform the reconfiguration and bus bandwidth reallocation necessary to support the new video format.

The device indicates its support for dynamic format change events through the VideoStreaming Header descriptor. See section 3.9.2.1 "Input Header Descriptor" and section 3.9.2.2 "Output Header Descriptor".

When a dynamic format change event occurs, the following steps take place:

- Device detects dynamic format change (while streaming is occurring).
- Device begins sending empty data payloads to the host with the Error bit set in the video stream payload header.
- Device sets the Stream Error Code Control to "Format Change" (see section 4.3.1.7 "Stream Error Code Control").
- The host queries the new stream state through a VS_PROBE_CONTROL request with the GET_CUR attribute (see 4.3.1.1, “Video Probe and Commit Controls”).
- If the new format is acceptable by the host, it issues a VS_COMMIT_CONTROL request with the SET_CUR attribute and, if necessary, reallocates the USB bandwidth through an alternate interface selection standard request. If the new format is not acceptable, the host will negotiate a new format with the stream PROBE/COMMIT controls.

2.4.3.7 Data Format Classes

For the purposes of host processing of incoming and outgoing data packets, the various video formats supported by the Video Device Class (VDC) can be divided into two broad categories:

- **Frame-based video formats** – These video formats require the frame/sample boundary information to be transmitted out-of-band. Examples of such formats are uncompressed video (formatted in various YUV variants), MJPEG, and DV. For these formats, the FID (and optionally EOF) bits in the VDC payload headers must be supported.
- **Stream-based video formats** – These video formats have the frame/sample boundary information transmitted in-band. Examples of such formats are MPEG-2 TS, PS and MPEG-1 system streams. For these formats, the FID and EOF bits do not need to be supported.

The following is determined by the format class under which the video format is classified:

- Incoming/Outgoing data processing algorithm by class driver
- Bit fields supported in VDC payload header (BFH[0])

The following is determined by the specific video payload format:

- Format descriptor type
- Frame descriptor type, if needed
- Support for time information fields in VDC payload header

Frame-based video formats:

- Uncompressed video (YUV variants) (*)
- MJPEG (*)
- DV (*)

Stream-based video formats:

- MPEG-1 System
- MPEG-2 TS
- MPEG-2 PS
- MPEG-4 SL

(*) Support for PTS and SCR fields in VDC payload header is required (see section 2.4.3.2.2, "Sample Isochronous Transfers").

2.4.4 Control Transfer and Request Processing

The Video Class specification's control transfer (or Request) mechanism builds upon sections 5.5, "Control Transfers"; 8.5.3 ,"Control Transfers; 9.2.6, "Request Processing"; and 9.3, "USB Device Requests" of the *Universal Serial Bus Specification, Revision 2.0* (the USB 2.0 spec). Those sections describe the timing and error handling of control transfers, but do not prescribe a method for control transfer completion using interrupt pipes. The following paragraphs describe Control Transfer operations in the context of the Video Class, including the use of the Status Interrupt pipe to provide notification of state changes within the device.

Control transfers minimally have two transaction stages: Setup and Status. A control transfer may optionally contain a Data stage between the Setup and Status stages. The Setup stage contains all information necessary to address a particular entity, specify the desired operation, and prepare for an optional Data stage. A Data stage can be host to device (OUT transactions), or device to host (IN transactions), depending on the direction and operation specified in the Setup stage via the **bmRequestType** and **bRequest** fields.

In the context of the Video Class specification, SET_CUR requests will always involve a Data stage from host to device, and GET_* requests will always involve a Data stage from device to host. Although none are defined currently, an exception to this rule would be a SET_CUR request where the **bRequest** field contains all information necessary to place the device into a known state. However, "toggle" requests without a Data stage are explicitly disallowed.

The device shall use *protocol stall* (not function stall) during the Data or Status stages if the device is unable to complete the Control transfer (see section 8.5.3.4 of the *USB Specification Revision 2.0*). Reasons for protocol stall include unsupported operations, invalid target entity, unexpected Data length, or invalid Data content. The device shall update the value of Request Error Code Control, and the host may use that control to determine the reason for the protocol

stall (see section 4.2.1.2 "Request Error Code Control"). The device must not NAK or STALL the SETUP transaction.

Typically, the host will serialize Control Transfers, meaning that the next Setup stage will not begin until the previous Status stage has completed. However, in situations where the bus has experienced errors, a Setup transaction may be sent before the completion of a previous control transfer. The device must abandon the previous control transfer.

Due to this command serialization, it is important that the duration of control transfers (from Setup stage through Status stage) be kept as short as possible. For this reason, as well as the desire to avoid polling for device status, the Video Class spec defines an interrupt status mechanism to convey status changes independently of the control transfers that caused the state change. This mechanism is described in section 2.4.2.2, "Status Interrupt Endpoint". Any control that requires more than 10ms to respond to a SET_CUR request (asynchronous control), or that can change independently of any external SET_CUR request (Autoupdate control), must send a Control Change status interrupt. These characteristics will be reflected in the GET_INFO response for that control (see 4.1.2, “Get Request”). In the case of a SET_CUR request for such a control, the Control Transfer operation shall enter the Status stage immediately after receiving the data transferred during the Data stage. Once the Status stage has successfully completed, the device must eventually send a Control Change interrupt. The amount of time between the end of a successful Status stage and the Control Change interrupt is implementation specific. For instance, a tape transport might take 3-5 seconds to completely change state, so the Control Change interrupt would be sent within 3-5 seconds.

If a SET_CUR request to an asynchronous control results in a stall, the device shall update the Request Error Code Control with the failure reason. In this case, the device shall not send a Control Change interrupt.

The following flow diagrams show the Setup, Data and Status stages of SET_CUR Control Transfers for controls supporting one of the two legal bit combinations with the D1 (SET) bit enabled. These are described because they show the relationship between a SET_CUR request and the resulting state change.

3 Descriptors

Descriptors are used by USB devices to report their attributes. A descriptor is a data structure with a defined format. For information, see section 9.5 Descriptors of *USB Specification Revision 2.0*.

The following sections describe the standard and class-specific USB descriptors for the Video Interface Class.

3.1 Descriptor Layout Overview

The following diagram illustrates the descriptor layout for an entire device. The example used in this case is for a desktop video camera device with a single isochronous video pipe and a dedicated bulk still image pipe.

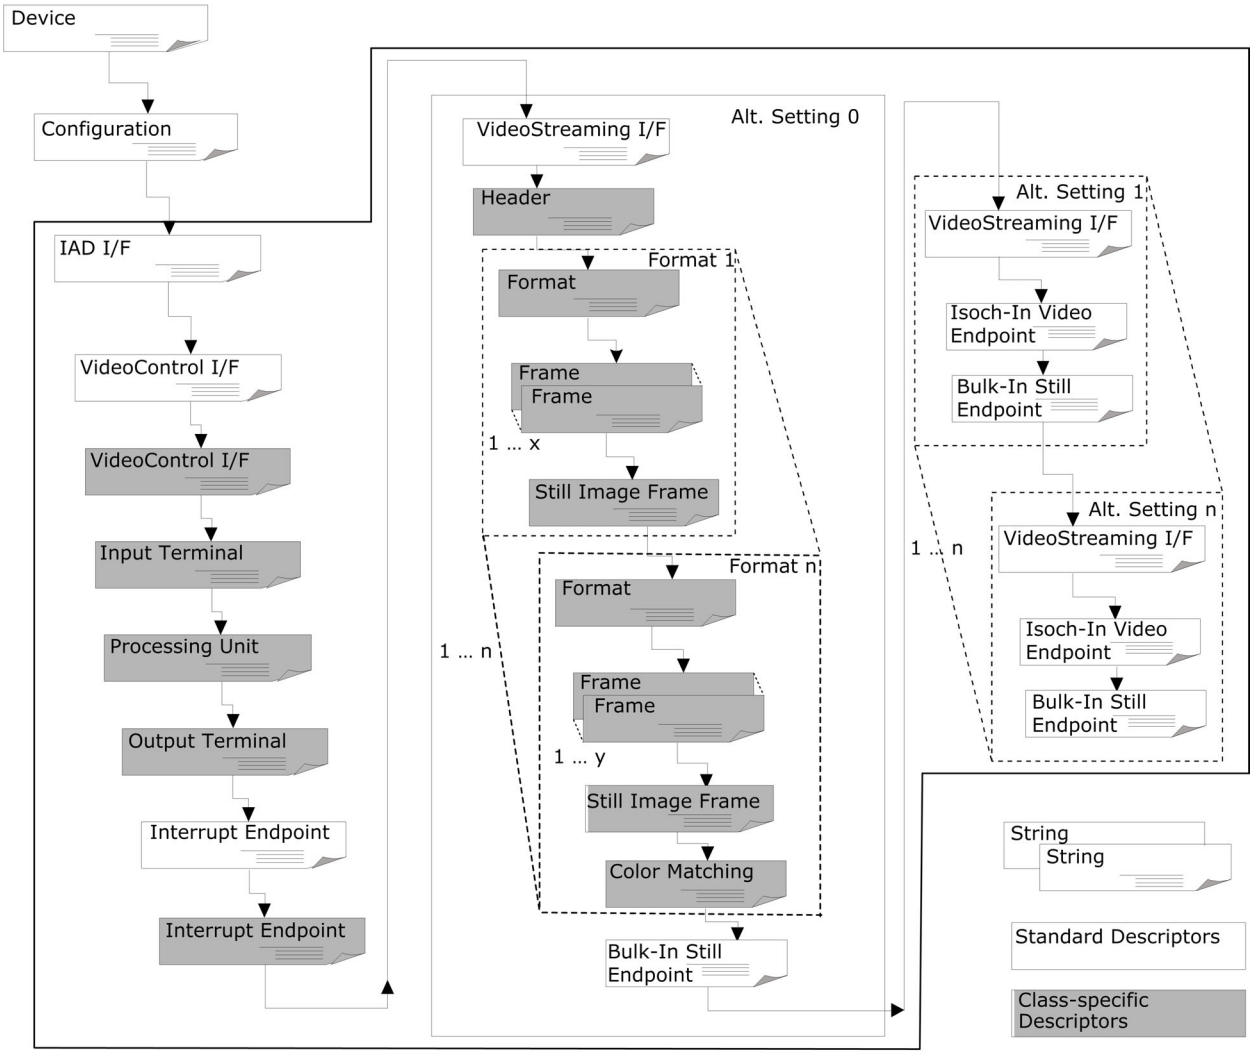

Figure 3-1 Video Camera Descriptor Layout Example

3.2 Device Descriptor

Because video functionality is always considered to reside at the interface level, this class specification does not define a specific video device descriptor.

For devices that contain a video function that only exposes a VideoControl Interface, the device descriptor must indicate that class information is to be found at the interface level. Therefore, the **bDeviceClass** field of the device descriptor must contain zero so that enumeration software

looks down at the interface level to determine the Interface Class. The **bDeviceSubClass** and **bDeviceProtocol** fields must be set to zero.

Devices that expose one or more Video Interface Collections also indicate that class information is to be found at the interface level. However, since the device uses an Interface Association Descriptor in order to describe the Video Interface Collection, it must set the **bDeviceClass**, **bDeviceSubClass** and **bDeviceProtocol** fields 0xEF, 0x02 and 0x01 respectively. This set of class codes is defined as the Multi-interface Function Class codes.

All other fields of the device descriptor must comply with the definitions in section 9.6.1 "Device" of *USB Specification Revision 2.0*. There is no class-specific device descriptor.

3.3 Device_Qualifier Descriptor

The Device_Qualifier descriptor is required for all USB 2.0 high-speed capable devices. The rules that apply for setting the **bDeviceClass**, **bDeviceSubClass** and **bDeviceProtocol** fields in the Device Descriptor apply for this descriptor as well. All other fields of the device qualifier descriptor must comply with the definitions in section 9.6.2 "Device Qualifier" of *USB Specification Revision 2.0.*

3.4 Configuration Descriptor

The configuration descriptor for a device containing a video function is identical to the standard Configuration descriptor defined in section 9.6.3 "Configuration" of *USB Specification Revision 2.0*. There is no class-specific configuration descriptor.

3.5 Other_Speed_Configuration Descriptor

The Other_Speed_Configuration descriptor is required for USB 2.0 devices that are capable of operating at both full-speed and high-speed modes. It is identical to the standard Other_Speed_Configuration descriptor defined in section 9.6.4 "Other_Speed_Configuration" of *USB Specification Revision 2.0.*

3.6 Interface Association Descriptor

A device must use an Interface Association Descriptor to describe a Video Interface Collection for each device function that requires a VideoControl Interface and one or more VideoStreaming interfaces. The standard VIC Interface Association Descriptor is identical to the standard Interface Association Descriptor defined in the *Interface Association Descriptor ECN*, except that some fields have now dedicated values.

Table 3-1 Standard Video Interface Collection IAD

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 8
1	**bDescriptorType**	1	Constant	INTERFACE ASSOCIATION Descriptor.

Offset	Field	Size	Value	Description
2	**bFirstInterface**	1	Number	Interface number of the first VideoControl interface that is associated with this function.
3	**bInterfaceCount**	1	Number	Number of contiguous VideoStreaming interfaces that are associated with this function. The count includes the first VideoControl interface and all its associated VideoStreaming interfaces.
4	**bFunctionClass**	1	Class	CC_VIDEO. Video Interface Class code (assigned by the USB). See section A.1, "Video Interface Class Code".
5	**bFunctionSubClass**	1	SubClass	SC_VIDEO_INTERFACE_COLLECTION. Video Interface Subclass code. Assigned by this specification. See section A.2, "Video Interface Subclass Codes".
6	**bFunctionProtocol**	1	Protocol	Not used. Must be set to PC_PROTOCOL_UNDEFINED.
7	**iFunction**	1	Index	Index of a string descriptor that describes this interface. This must be used for the device (function) name and be implemented in US English (LANGID = 0x0409) at the minimum.

3.7 VideoControl Interface Descriptors

The VideoControl (VC) interface descriptors contain all relevant information to fully characterize the corresponding video function. The standard interface descriptor characterizes the interface itself, whereas the class-specific interface descriptor provides pertinent information concerning the internals of the video function. It specifies revision level information and lists the capabilities of each Unit and Terminal.

3.7.1 Standard VC Interface Descriptor

The standard VC interface descriptor is identical to the standard interface descriptor defined in section 9.6.5 "Interface" of *USB Specification Revision 2.0*, except that some fields have now dedicated values.

Table 3-2 Standard VC Interface Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 9
1	**bDescriptorType**	1	Constant	INTERFACE descriptor type
2	**bInterfaceNumber**	1	Number	Number of interface. A zero-based value identifying the index in the array of concurrent interfaces supported by this configuration.

3	**bAlternateSetting**	1	Number	Value used to select an alternate setting for the interface identified in the prior field.
4	**bNumEndpoints**	1	Number	Number of endpoints used by this interface (excluding endpoint 0). This number is 0 or 1 depending on whether the optional status interrupt endpoint is present.
5	**bInterfaceClass**	1	Class	CC_VIDEO. Video Interface Class code (assigned by the USB). See section A.1, "Video Interface Class Code".
6	**bInterfaceSubClass**	1	Subclass	SC_VIDEOCONTROL. Video Interface Subclass code. Assigned by this specification. See section A.2, "Video Interface Subclass Codes".
7	**bInterfaceProtocol**	1	Protocol	Not used. Must be set to PC_PROTOCOL_UNDEFINED.
8	**iInterface**	1	Index	Index of a string descriptor that describes this interface. This must be used for the device (function) name and be implemented in US English (LANGID = 0x0409) at the minimum.

3.7.2 Class-Specific VC Interface Descriptor

The class-specific VC interface descriptor is a concatenation of all the descriptors that are used to fully describe the video function, i.e., all Unit Descriptors (UDs) and Terminal Descriptors (TDs).

The total length of the class-specific VC interface descriptor depends on the number of Units and Terminals in the video function. Therefore, the descriptor starts with a header that reflects the total length in bytes of the entire class-specific VC interface descriptor in the **wTotalLength** field. The **bcdVDC** field identifies the release of the Video Device Class Specification with which this video function and its descriptors are compliant. The **bInCollection** field indicates how many VideoStreaming interfaces there are in the Video Interface Collection to which this VideoControl interface belongs. The **baInterfaceNr()** array contains the interface numbers of all the VideoStreaming interfaces in the Collection. The **bInCollection** and **baInterfaceNr()** fields together provide all necessary information to determine which interfaces together constitute the entire USB interface to the video function, i.e., describe the Video Interface Collection.

The order in which the Unit and Terminal descriptors are reported is not important, because every descriptor can be identified through its **bDescriptorType** and **bDescriptorSubtype** fields. The **bDescriptorType** field identifies the descriptor as being a class-specific interface descriptor. The **bDescriptorSubtype** field further qualifies the exact nature of the descriptor.

The following table defines the class-specific VC interface header descriptor.

Table 3-3 Class-specific VC Interface Header Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 12+n
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubType**	1	Constant	VC_HEADER descriptor subtype
3	**bcdVDC**	2	BCD	Video Device Class Specification release number in binary-coded decimal. (i.e. 2.10 is 210H)
5	**wTotalLength**	2	Number	Total number of bytes returned for the class-specific VideoControl interface descriptor. Includes the combined length of this descriptor header and all Unit and Terminal descriptors.
7	**dwClockFrequency**	4	Number	The device clock frequency in Hz. This will specify the units used for the time information fields in the Video Sample Headers in the data stream.
11	**bInCollection**	1	Number	The number of VideoStreaming interfaces in the Video Interface Collection to which this VideoControl interface belongs: n
12	**baInterfaceNr(1)**	1	Number	Interface number of the first VideoStreaming interface in the Collection
…	**…**	…	…	…
12+(n-1)	**baInterfaceNr(n)**	1	Number	Interface number of the last VideoStreaming interface in the Collection

This header is followed by one or more Unit and/or Terminal Descriptors. The layout of the descriptors depends on the type of Unit or Terminal they represent. There is a descriptor type for each Unit and Terminal described in section 2.3, "Video Function Topology". They are summarized in the following sections. The first four fields are common for all Unit and Terminal Descriptors. They contain the Descriptor Length, Descriptor Type, Descriptor Subtype, and Unit or Terminal ID.

Each Unit and Terminal within the video function is assigned a unique identification number, the Unit ID (UID) or Terminal ID (TID), contained in the **bUnitID** or **bTerminalID** field of the descriptor. The value 0x00 is reserved for undefined ID, effectively restricting the total number of addressable entities in the video function (both Units and Terminals) to 255.

Besides uniquely identifying all addressable entities in a video function, the IDs also serve to describe the topology of the video function; i.e., the **bSourceID** field of a Unit or Terminal descriptor indicates to which other Unit or Terminal this Unit or Terminal is connected.

3.7.2.1 Input Terminal Descriptor

The Input Terminal descriptor (ITD) provides information to the Host that is related to the functional aspects of the Input Terminal.

The Input Terminal is uniquely identified by the value in the **bTerminalID** field. No other Unit or Terminal within the same video function may have the same ID. This value must be passed in the **bTerminalID** field of each request that is directed to the Terminal.

The **wTerminalType** field provides pertinent information about the physical entity that the Input Terminal represents. This could be a USB OUT endpoint, an external Composite Video In connection, a camera sensor, etc. A complete list of Terminal Type codes is provided in section B.2, "Input Terminal Types".

The **bAssocTerminal** field is used to associate an Output Terminal to this Input Terminal, effectively implementing a bi-directional Terminal pair. An example of this would be a tape unit on a camcorder, which would have Input and Output Terminals to sink and source video respectively. If the **bAssocTerminal** field is used, both associated Terminals must belong to the bi-directional Terminal Type group. If no association exists, the **bAssocTerminal** field must be set to zero.

The Host software can treat the associated Terminals as being physically related. In many cases, one Terminal can not exist without the other. An index to a string descriptor is provided to further describe the Input Terminal.

The following table presents an outline of the Input Terminal descriptor.

Table 3-4 Input Terminal Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 8 (+ x)
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubtype**	1	Constant	VC_INPUT_TERMINAL descriptor subtype
3	**bTerminalID**	1	Constant	A non-zero constant that uniquely identifies the Terminal within the video function. This value is used in all requests to address this Terminal.
4	**wTerminalType**	2	Constant	Constant that characterizes the type of Terminal. See Appendix B, "Terminal Types".
6	**bAssocTerminal**	1	Constant	ID of the Output Terminal to which this Input Terminal is associated.
7	**iTerminal**	1	Index	Index of a string descriptor, describing the Input Terminal.
…	…	…	…	Depending on the Terminal type, certain Input Terminal descriptors have additional fields. The descriptors for these special Terminal

				types are described in separate sections specific to those Terminals.

3.7.2.2 Output Terminal Descriptor

The Output Terminal descriptor (OTD) provides information to the Host that is related to the functional aspects of the Output Terminal.

The Output Terminal is uniquely identified by the value in the **bTerminalID** field. No other Unit or Terminal within the same video function may have the same ID. This value must be passed in the **bTerminalID** field of each request that is directed to the Terminal.

The **wTerminalType** field provides pertinent information about the physical entity the Output Terminal represents. This could be a USB IN endpoint, an external Composite Video Out connection, a LCD display, etc. A complete list of Terminal Type codes is provided in section B.3, "Output Terminal Types".

The **bAssocTerminal** field is used to associate an Input Terminal to this Output Terminal, effectively implementing a bi-directional Terminal pair. If the **bAssocTerminal** field is used, both associated Terminals must belong to the bi-directional Terminal Type group. If no association exists, the **bAssocTerminal** field must be set to zero.

The **bSourceID** field is used to describe the connectivity for this Terminal. It contains the ID of the Unit or Terminal to which this Output Terminal is connected via its Input Pin.
An index to a string descriptor is provided to further describe the Output Terminal.

The following table presents an outline of the Output Terminal descriptor.

Table 3-5 Output Terminal Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 9 (+ x)
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubtype**	1	Constant	VC_OUTPUT_TERMINAL descriptor subtype
3	**bTerminalID**	1	Constant	A non-zero constant that uniquely identifies the Terminal within the video function. This value is used in all requests to address this Terminal.
4	**wTerminalType**	2	Constant	Constant that characterizes the type of Terminal. See Appendix B, "Terminal Types".
6	**bAssocTerminal**	1	Constant	Constant, identifying the Input Terminal to which this Output Terminal is associated.
7	**bSourceID**	1	Constant	ID of the Unit or Terminal to which this

				Terminal is connected.
8	**iTerminal**	1	Index	Index of a string descriptor, describing the Output Terminal.
…	…	…	…	Depending on the Terminal type, certain Output Terminal descriptors have additional fields. The descriptors for these special Terminal types are described in accompanying documents.

3.7.2.3 Camera Terminal Descriptor

The Camera Terminal is uniquely identified by the value in the **bTerminalID** field. No other Unit or Terminal within the same video function may have the same ID. This value must be passed in the **bTerminalID** field of each request that is directed to the Terminal.

The **wTerminalType** field provides pertinent information about the physical entity that the Input Terminal represents. For the Camera Terminal, this field shall be set to the Sensor terminal type.

The **bAssocTerminal** field is used to associate an Output Terminal to this Input Terminal, effectively implementing a bi-directional Terminal pair. An index to a string descriptor is provided to further describe the Camera Terminal.

The **bmControls** field is a bitmap, indicating the availability of certain camera controls for the video stream. For future expandability, the number of bytes occupied by the **bmControls** field is indicated in the **bControlSize** field. The **bControlSize** field is permitted to specify a value less than three (including zero), in which case the unspecified bmControls bytes will not be present and the corresponding control bits are assumed to be zero.

The layout of the Camera Terminal descriptor is detailed in the following table.

Table 3-6 Camera Terminal Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 15 + n
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubtype**	1	Constant	VC_INPUT_TERMINAL descriptor subtype
3	**bTerminalID**	1	Constant	A non-zero constant that uniquely identifies the Terminal within the video function. This value is used in all requests to address this Terminal.
4	**wTerminalType**	2	Constant	Constant that characterizes the type of Terminal. This is set to the

				ITT_CAMERA value.
6	**bAssocTerminal**	1	Constant	ID of the Output Terminal to which this Input Terminal is associated.
7	**iTerminal**	1	Index	Index of a string descriptor that describes the Camera Terminal.
8	**wObjectiveFocalLengthMin**	2	Number	The value of L_{min} (see section 2.4.2.5.1 "Optical Zoom"). If Optical Zoom is not supported, this field shall be set to 0.
10	**wObjectiveFocalLengthMax**	2	Number	The value of L_{max} (see section 2.4.2.5.1 "Optical Zoom"). If Optical Zoom is not supported, this field shall be set to 0.
12	**wOcularFocalLength**	2	Number	The value of L_{ocular} (see section 2.4.2.5.1 "Optical Zoom"). If Optical Zoom is not supported, this field shall be set to 0.
14	**bControlSize**	1	Number	Size in bytes of the **bmControls** field: n
15	**bmControls**	n	Bitmap	A bit set to 1 indicates that the mentioned Control is supported for the video stream. D0: Scanning Mode D1: Auto-Exposure Mode D2: Auto-Exposure Priority D3: Exposure Time (Absolute) D4: Exposure Time (Relative) D5: Focus (Absolute) D6 : Focus (Relative) D7: Iris (Absolute) D8 : Iris (Relative) D9: Zoom (Absolute) D10: Zoom (Relative) D11: PanTilt (Absolute) D12: PanTilt (Relative) D13: Roll (Absolute) D14: Roll (Relative) D15: Reserved D16: Reserved D17: Focus, Auto D18: Privacy D19..(n*8-1): Reserved

3.7.2.4 Selector Unit Descriptor

The Selector Unit is uniquely identified by the value in the **bUnitID** field of the Selector Unit descriptor (SUD). No other Unit or Terminal within the same video function may have the same ID. This value must be passed with each request that is directed to the Selector Unit.

The **bNrInPins** field contains the number of Input Pins *(*p) of the Selector Unit. The connectivity of the Input Pins is described via the **baSourceID()** array that contains *p* elements. The index *i* into the array is one-based and directly related to the Input Pin numbers. **baSourceID(i)** contains the ID of the Unit or Terminal to which Input Pin *i* is connected.

An index to a string descriptor is provided to further describe the Selector Unit.

The following table details the structure of the Selector Unit descriptor.

Table 3-7 Selector Unit Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 6+p
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubtype**	1	Constant	VC_SELECTOR_UNIT descriptor subtype
3	**bUnitID**	1	Number	A non-zero constant that uniquely identifies the Unit within the video function. This value is used in all requests to address this Unit.
4	**bNrInPins**	1	Number	Number of Input Pins of this Unit: p
5	**baSourceID(1)**	1	Number	ID of the Unit or Terminal to which the first Input Pin of this Selector Unit is connected.
…	**…**	…	…	…
5+(p-1)	**baSourceID(p)**	1	Number	ID of the Unit or Terminal to which the last Input Pin of this Selector Unit is connected.
5+p	**iSelector**	1	Index	Index of a string descriptor, describing the Selector Unit.

3.7.2.5 Processing Unit Descriptor

The Processing Unit is uniquely identified by the value in the **bUnitID** field of the Processing Unit descriptor (PUD). No other Unit or Terminal within the same video function may have the same ID. This value must be passed with each request that is directed to the Processing Unit.

The **bSourceID** field is used to describe the connectivity for this Processing Unit. It contains the ID of the Unit or Terminal to which this Processing Unit is connected via its Input Pin. The **bmControls field** is a bit-map, indicating the availability of certain processing Controls for the video stream. For future expandability, the number of bytes occupied by the **bmControls** field is indicated in the **bControlSize** field. The **bControlSize** field is permitted to specify a value less

than two (including zero), in which case the unspecified bmControls bytes will not be present and the corresponding control bits are assumed to be zero.

An index to a string descriptor is provided to further describe the Processing Unit.

The layout of the Processing Unit descriptor is detailed in the following table.

Table 3-8 Processing Unit Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 9+n
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubtype**	1	Constant	VC_PROCESSING_UNIT descriptor subtype
3	**bUnitID**	1	Number	A non-zero constant that uniquely identifies the Unit within the video function. This value is used in all requests to address this Unit.
4	**bSourceID**	1	Constant	ID of the Unit or Terminal to which this Unit is connected.
5	**wMaxMultiplier**	2	Number	If the Digital Multiplier control is supported, this field indicates the maximum digital magnification, multiplied by 100. For example, for a device that supports 1-4.5X digital zoom (a multiplier of 4.5), this field would be set to 4500. If the Digital Multiplier control is not supported, this field shall be set to 0.
7	**bControlSize**	1	Number	Size of the **bmControls** field, in bytes: n
8	**bmControls**	n	Bitmap	A bit set to 1 indicates that the mentioned Control is supported for the video stream. D0: Brightness D1: Contrast D2: Hue D3: Saturation D4: Sharpness D5: Gamma D6: White Balance Temperature D7: White Balance Component D8: Backlight Compensation D9: Gain D10: Power Line Frequency D11: Hue, Auto D12: White Balance Temperature, Auto D13: White Balance Component, Auto D14: Digital Multiplier

				D15: Digital Multiplier Limit
8+n	**iProcessing**	1	Index	Index of a string descriptor that describes this processing unit.

3.7.2.6 Extension Unit Descriptor

The Extension Unit is uniquely identified by the value in the **bUnitID** field of the Extension Unit descriptor (XUD). No other Unit or Terminal within the same video function may have the same ID. This value must be passed with each request that is directed to the Extension Unit.

The Extension Unit descriptor provides minimal information about the Extension Unit for a generic driver at least to notice the presence of vendor-specific components within the video function. The **guidExtensionCode** field contains a vendor-specific code that further identifies the Extension Unit.

The **bNrInPins** field contains the number of Input Pins *(*p) of the Extension Unit. The connectivity of the Input Pins is described via the **baSourceID()** array that contains *p* elements. The index *i* into the array is one-based and directly related to the Input Pin numbers. **baSourceID(i)** contains the ID of the Unit or Terminal to which Input Pin *i* is connected.

The **bmControls** field is a bitmap, indicating the availability of certain video Controls in the Extension Unit. For future expandability, the number of bytes occupied by the **bmControls** field is indicated in the **bControlSize** field. All Controls are optional.

An index to a string descriptor is provided to further describe the Extension Unit.

The following table outlines the Extension Unit descriptor.

Table 3-9 Extension Unit Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 24+p+n
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubtype**	1	Constant	VC_EXTENSION_UNIT descriptor subtype
3	**bUnitID**	1	Number	A non-zero constant that uniquely identifies the Unit within the video function. This value is used in all requests to address this Unit.
4	**guidExtensionCode**	16	GUID	Vendor-specific code identifying the Extension Unit
20	**bNumControls**	1	Number	Number of controls in this extension unit
21	**bNrInPins**	1	Number	Number of Input Pins of this Unit: p
22	**baSourceID(1)**	1	Number	ID of the Unit or Terminal to which the first Input Pin of this Extension Unit is

				connected.
…	**…**	…	…	…
22+(p-1)	**baSourceID(p)**	1	Number	ID of the Unit or Terminal to which the last Input Pin of this Extension Unit is connected.
22+p	**bControlSize**	1	Number	Size of the **bmControls** field, in bytes: n
23+p	**bmControls**	n	Bitmap	A bit set to 1 indicates that the mentioned Control is supported: D(n*8-1)..0: Vendor-specific
23+p+n	**iExtension**	1	Index	Index of a string descriptor that describes this extension unit.

3.8 VideoControl Endpoint Descriptors

The following sections describe all possible endpoint-related descriptors for the VideoControl interface.

3.8.1 VC Control Endpoint Descriptors

3.8.1.1 Standard VC Control Endpoint Descriptor

Because endpoint 0 is used as the VideoControl control endpoint, there is no dedicated standard control endpoint descriptor.

3.8.1.2 Class-Specific VC Control Endpoint Descriptor

There is no dedicated class-specific control endpoint descriptor.

3.8.2 VC Interrupt Endpoint Descriptors

The standard and class-specific Interrupt Endpoint descriptors provide all information about the device interrupt usage.

3.8.2.1 Standard VC Interrupt Endpoint Descriptor

The interrupt endpoint descriptor is identical to the standard endpoint descriptor defined in section 9.6.6 "Endpoint" of *USB Specification Revision 2.0*. Its fields are set to reflect the interrupt type of the endpoint. This endpoint is optional.

The following table outlines the standard VC Interrupt Endpoint descriptor.

Table 3-10 Standard VC Interrupt Endpoint Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 7
1	**bDescriptorType**	1	Constant	ENDPOINT descriptor type
2	**bEndpointAddress**	1	Endpoint	The address of the endpoint on the USB device described by this descriptor. The address is encoded as follows: D7: Direction. 1 = IN endpoint D6..4: Reserved, reset to zero. D3..0: The endpoint number, determined by the designer.
3	**bmAttributes**	1	Bitmap	D3..2: Synchronization type. Must be set to 00 (None) D1..0: Transfer type. Must be set to 11 (Interrupt). All other bits are reserved.
4	**wMaxPacketSize**	2	Number	Maximum packet size this endpoint is capable of sending or receiving when this configuration is selected. Used here to pass 4-byte status information.
6	**bInterval**	1	Number	Interval for polling endpoint for data transfers. For full-speed devices, this value is expressed in frames, and must range from 1 to 255. For high-speed devices, this value is expressed in microframes, and must range from 1 to 16.The bInterval value is used as the exponent for a $2^{bInterval-1}$ period. Actual value is left to the designer's discretion. A value of equivalent to 10ms or more seems sufficient.

3.8.2.2 Class-specific VC Interrupt Endpoint Descriptor

The class-specific interrupt endpoint descriptor provides information about the maximum interrupt structure size that the device is capable of sending. The host driver will use this value to allocate a buffer of sufficient size to receive the maximum interrupt structure size. This descriptor is mandatory if the standard interrupt endpoint descriptor is defined.

Table 3-11 Class-specific VC Interrupt Endpoint Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 5

1	**bDescriptorType**	1	Constant	CS_ENDPOINT descriptor type
2	**bDescriptorSubType**	1	Constant	EP_INTERRUPT descriptor type
3	**wMaxTransferSize**	2	Number	Maximum interrupt structure size this endpoint is capable of sending.

3.9 VideoStreaming Interface Descriptors

The VideoStreaming (VS) interface descriptors contain all relevant information to characterize the VideoStreaming interface in full.

3.9.1 Standard VS Interface Descriptor

The standard VS interface descriptor is identical to the standard interface descriptor defined in section 9.6.5 "Interface" of *USB Specification Revision 2.0*, except that some fields now have dedicated values.

Table 3-12 Standard VS Interface Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 9
1	**bDescriptorType**	1	Constant	INTERFACE descriptor type
2	**bInterfaceNumber**	1	Number	Number of the interface. A zero-based value identifying the index in the array of concurrent interfaces supported by this configuration.
3	**bAlternateSetting**	1	Number	Value used to select an alternate setting for the interface identified in the prior field.
4	**bNumEndpoints**	1	Number	Number of endpoints used by this interface (excluding endpoint 0).
5	**bInterfaceClass**	1	Class	CC_VIDEO. Video Interface Class code (assigned by the USB). See section A.1, "Video Interface Class Code".
6	**bInterfaceSubClass**	1	subclass	SC_VIDEOSTREAMING. Video interface subclass code (assigned by this specification). See section A.2, "Video Interface Subclass Codes".
7	**bInterfaceProtocol**	1	Protocol	Not used. Must be set to PC_PROTOCOL_UNDEFINED.
8	**iInterface**	1	Index	Index of a string descriptor that describes this interface.

3.9.2 Class-Specific VS Interface Descriptors

The class-specific VS interface descriptors consist of Input Header, Output Header, Format and Frame descriptors.

There is a single Input or Output Header descriptor for each VS interface, and a separate Format descriptor for each supported video stream format and a separate list of Frame descriptors for each Format descriptor. Header, Format and Frame descriptors are only defined in alternate setting 0 of the relevant interface. They are not repeated within subsequent alternate settings of the same interface.

3.9.2.1 Input Header Descriptor

The Input Header descriptor is used for VS interfaces that contain an IN endpoint for streaming video data. It provides information on the number of different format descriptors that will follow it, as well as the total size of all class-specific descriptors in alternate setting zero of this interface.

The following table defines the class-specific VS interface Input Header descriptor.

Table 3-13 Class-specific VS Interface Input Header Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 13+(p*n).
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubtype**	1	Constant	VS_INPUT_HEADER descriptor subtype
3	**bNumFormats**	1	Number	Number of video payload format descriptors following for this interface (excluding video frame descriptors): p
4	**wTotalLength**	2	Number	Total number of bytes returned for the class-specific VideoStreaming interface descriptors including this header descriptor.
6	**bEndpointAddress**	1	Endpoint	The address of the isochronous or bulk endpoint used for video data. The address is encoded as follows: D7: Direction 1 = IN endpoint D6..4: Reserved, reset to zero. D3..0: The endpoint number, determined by the designer.
7	**bmInfo**	1	Bitmap	Indicates the capabilities of this VideoStreaming interface: D0: Dynamic Format Change supported D7..1: Reserved
8	**bTerminalLink**	1	Constant	The terminal ID of the Output Terminal to which the video endpoint of this interface is connected.
9	**bStillCaptureMethod**	1	Number	Method of still image capture supported as described in section 2.4.2.4, "Still Image

				Capture": 0: None (Host software will not support any form of still image capture) 1: Method 1 2: Method 2 3: Method 3
10	**bTriggerSupport**	1	Number	Specifies if hardware triggering is supported through this interface 0: Not supported 1: Supported
11	**bTriggerUsage**	1	Number	Specifies how the host software shall respond to a hardware trigger interrupt event from this interface. This is ignored if the bTriggerSupport field is zero. 0: Initiate still image capture 1: General purpose button event. Host driver will notify client application of button press and button release events
12	**bControlSize**	1	Number	Size of each **bmaControls(x)** field, in bytes: n
13	**bmaControls(1)**	n	Bitmap	A bit set to 1 indicates that the mentioned control is supported for the VideoStreaming interface when Format Index 1 is selected: D0: Key frame rate D1: P frame rate D2: Compression quality D3: Compression window size D4: Generate Key Frame D5: Update Frame Segment D6..(n*8-1): Reserved
…	**…**	…	…	…
13+ (p*n-n)	**bmaControls(p)**	n	Bitmap	A bit set to 1 indicates that the mentioned control is supported for the VideoStreaming interface when Format Index p is selected: D0: Key frame rate D1: P frame rate D2: Compression quality D3: Compression window size D4: Generate Key Frame D5: Update Frame Segment D6..(n*8-1): Reserved

3.9.2.2 Output Header Descriptor

The Output Header descriptor is used for VS interfaces that contain an OUT endpoint for streaming video data. It provides information on the number of different format descriptors that will follow it, as well as the total size of all class-specific descriptors in alternate setting zero of this interface.

The following table defines the class-specific VS interface output header descriptor:

Table 3-14 Class-specific VS Interface Output Header Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 8
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubtype**	1	Constant	VS_OUTPUT_HEADER descriptor subtype
3	**bNumFormats**	1	Number	Number of video payload format descriptors following for this interface (excluding video frame descriptors).
4	**wTotalLength**	2	Number	Total number of bytes returned for the class-specific VideoStreaming interface descriptors including this header descriptor.
6	**bEndpointAddress**	1	Endpoint	The address of the isochronous or bulk endpoint used for video data. The address is encoded as follows: D7: Direction 0 = OUT endpoint D6..4: Reserved, reset to zero D3..0: The endpoint number, determined by the designer.
7	**bTerminalLink**	1	Constant	The terminal ID of the Input Terminal to which the video endpoint of this interface is connected.

3.9.2.3 Payload Format Descriptors

A Payload Format descriptor defines the characteristics of a video stream with its specific format. The following descriptors are defined in the separate Payload Specification documents that accompany this document. For more information about a specific descriptor, see the corresponding document.

Table 3-15 Payload Format Descriptor

Payload Format Descriptor	Document
Uncompressed Video	USB_Video_Payload_Uncompressed

MJPEG Video	USB_Video_Payload_MJPEG
MPEG1 System Stream	USB_Video_Payload_MPEG1-SS_MPEG2-PS
MPEG2 PS	USB_Video_Payload_MPEG1-SS_MPEG2-PS
MPEG-2 TS	USB_Video_Payload_MPEG2-TS
MPEG-4 SL	USB_Video_Payload_MPEG4-SL
DV	USB_Video_Payload_DV
Vendor Defined	USB_Video_Payload_Vendor

3.9.2.4 Video Frame Descriptor

A Video Frame descriptor (or Frame descriptor for short) is used to describe the decoded video and still image frame dimensions and other frame-specific characteristics supported by a stream with its specific format.

The following Video Frame descriptors are defined in the separate Payload Specification documents that accompany this document. For more information about a specific frame descriptor, see the corresponding document.

Table 3-16 Defined Video Frame Descriptor Resources

Video Frame Descriptor	Document
Uncompressed	USB_Video_Payload_Uncompressed
MJPEG	USB_Video_Payload_MJPEG

3.9.2.5 Still Image Frame Descriptor

The Still Image Frame descriptor is only applicable for a VS interface that supports method 2 or 3 of still image capture in conjunction with frame-based Payload formats (e.g., MJPEG, uncompressed, etc.). The Still Image Frame descriptor defines the characteristics of the still image capture for these frame-based formats. A single still Image Frame descriptor follows the Frame descriptor(s) for each Format descriptor group. If the Input Header descriptor's **bStillCaptureMethod** field is set to method 2 or 3, this Still Image Frame descriptor shall be defined (see section 3.9.2.1, "Input Header Descriptor").

The Still Image Frame descriptor contains the range of image sizes available from the device, which comprise the list of possible still image formats. To select a particular still image format, host software sends control requests to the corresponding interface (see section 4.3.1.2, "

Video Still Probe Control and Still Commit Control").

The Still Image Frame descriptor is shown in Table 3-17 Still Image Frame Descriptor below.

The **bEndpointAddress** field contains the bulk endpoint address within the related VS interface that is used for still image capture. The endpoint always functions as an IN-Endpoint.

The **wWidth(x)** and **wHeight(x)** fields form an array of image sizes supported by the device, measured in pixels of an uncompressed image.

The **bNumImageSizePattern**s represents the number of **wWidth** and **wHeight** pairs in the array.

The **bCompression** field represents the image quality that would be generated by the device. The range of compression values is from 0 to 255. A small value indicates a low compression ratio and high quality image. The default setting of this value depends on device implementation. The **bCompression(x)** fields form an array of compression ratios supported by device for all image sizes. The **bNumCompressionPatterns** field represents the number of **bCompression** fields in this array**.**

A Still Image Frame descriptor identifies the following:

Table 3-17 Still Image Frame Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 10+(4*n)-4+m
1	**bDescriptorType**	1	Constant	CS_INTERFACE descriptor type
2	**bDescriptorSubtype**	1	Constant	VS_STILL_IMAGE_FRAME descriptor subtype
3	**bEndpointAddress**	1	Endpoint	If method 3 of still image capture is used, this contains the address of the bulk endpoint used for still image capture. The address is encoded as follows: D7: Direction. (set to 1 = IN endpoint) D6..4: Reserved, reset to zero D3..0: The endpoint number, determined by the designer If method 2 of still image capture is used, this field shall be set to zero.
4	**bNumImageSizePatterns**	1	Number	Number of Image Size patterns of this format: n
5	**wWidth(1)**	2	Number	Width of the still image in pattern 1
7	**wHeight(1)**	2	Number	Height of the still image in pattern 1
…	**…**	…	…	…

…	**…**	…	…	…
5+4*n-4	**wWidth(n)**	2	Number	Width of the still image in pattern n
7+4*n-4	**wHeight(n)**	2	Number	Height of the still image in pattern n
9+4*n-4	**bNumCompression Pattern**	1	Number	Number of Compression pattern of this format: m
10+4*n-4	**bCompression(1)**	1	Number	Compression of the still image in pattern 1
…	**…**	…	…	…
10+4*n-4+m-1	**bCompression(m)**	1	Number	Compression of the still image in pattern m

3.9.2.6 Color Matching Descriptor

The Color Matching descriptor is an optional descriptor used to describe the color profile of the video data in an unambiguous way. Only one instance is allowed for a given format and if present, the Color Matching descriptor shall be placed following the Video and Still Image Frame descriptors for that format.

For example, this descriptor would be used with Uncompressed Video, MJPEG and MPEG-1 formats. It would not be used in the case MPEG-2, DV or MPEG-4 because the information is already available implicitly (DV) or explicitly (MPEG-2, MPEG-4). If a format requires this descriptor, the corresponding payload specification must enforce this requirement.
In the absence of this descriptor, or in the case of "Unspecified" values within the descriptor, color matching defaults will be assumed. The color matching defaults are compliant with sRGB since the BT.709 transfer function and the sRGB transfer function are very similar.

The viewing conditions and monitor setup are implicitly based on sRGB and the device should compensate for them (D50 ambient white, dim viewing or 64 lux ambient illuminance, 2.2 gamma reference CRT, etc).

Table 3-18 Color Matching Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Constant	6
1	**bDescriptorType**	1	Number	CS_INTERFACE type
2	**bDescriptorSubtype**	1	Number	VS_COLORFORMAT
3	**bColorPrimaries**	1	Number	This defines the color primaries and the reference white. 0: Unspecified (Image characteristics unknown) 1: BT.709, sRGB (default) 2: BT.470-2 (M)

				3: BT.470-2 (B, G) 4: SMPTE 170M 5: SMPTE 240M 6-255: Reserved
4	**bTransferCharacteristics**	1	Number	This field defines the opto-electronic transfer characteristic of the source picture also called the gamma function. 0: Unspecified (Image characteristics unknown) 1: BT.709 (default) 2: BT.470-2 M 3: BT.470-2 B, G 4: SMPTE 170M 5: SMPTE 240M 6: Linear (V = Lc) 7: sRGB (very similar to BT.709) 8-255: Reserved
5	**bMatrixCoefficients**	1	Number	Matrix used to compute luma and chroma values from the color primaries. 0: Unspecified (Image characteristics unknown) 1: BT. 709 2: FCC 3: BT.470-2 B, G 4: SMPTE 170M (BT.601, default) 5: SMPTE 240M 6-255: Reserved

3.10 VideoStreaming Endpoint Descriptors

The following sections describe all possible endpoint-related descriptors for the VideoStreaming interface.

3.10.1 VS Video Data Endpoint Descriptors

The video data endpoint can be implemented as either an isochronous or bulk endpoint. The standard isochronous or bulk endpoint descriptor provides pertinent information about how video data streams are communicated to the video function. In addition, specific endpoint capabilities and properties are reported.

3.10.1.1 Standard VS Isochronous Video Data Endpoint Descriptor

The standard VS isochronous video data endpoint descriptor is identical to the standard endpoint descriptor defined in section 9.6.6 "Endpoint" of *USB Specification Revision 2.0*. D7 of the **bEndpointAddress** field indicates whether the endpoint is a video source (D7 = 1) or a video sink (D7 = 0). The **bmAttributes** field bits are set to reflect the isochronous type of the endpoint. The synchronization type is indicated by D3..2 and must be set to Asynchronous. For further details, refer to section 5.12.4.1 "Synchronization Type," of *USB Specification Revision 2.0*.

Table 3-19 Standard VS Isochronous Video Data Endpoint Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 7
1	**bDescriptorType**	1	Constant	ENDPOINT descriptor type
2	**bEndpointAddress**	1	Endpoint	The address of the endpoint on the USB device described by this descriptor. The address is encoded as follows: D7: Direction 0 = OUT endpoint 1 = IN endpoint D6..4: Reserved, reset to zero D3..0: The endpoint number, determined by the designer
3	**bmAttributes**	1	Bitmap	D3..2: Synchronization type 01 = Asynchronous D1..0: Transfer type 01 = Isochronous All other bits are reserved.
4	**wMaxPacketSize**	2	Number	Maximum packet size this endpoint is capable of sending or receiving when this configuration is selected. This is determined by the video bandwidth constraints of the endpoint.
6	**bInterval**	1	Number	Interval for polling endpoint for data transfers. This value is expressed as a period of frames or microframes depending on device speed, and must range from 1 to 16. The bInterval value is used as the exponent for a $2^{bInterval-1}$ period.

3.10.1.2 Standard VS Bulk Video Data Endpoint Descriptor

The standard VS Bulk video data endpoint descriptor is identical to the standard endpoint descriptor defined in section 9.6.6 "Endpoint" of *USB Specification Revision 2.0*. D7 of the

bEndpointAddress field indicates that this endpoint is a data source (D7 = 1) or a video sink (D7 = 0). The **bmAttributes** field bits are set to reflect the bulk type of the endpoint.

Table 3-20 Standard VS Bulk Video Data Endpoint Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 7
1	**bDescriptorType**	1	Constant	ENDPOINT descriptor type
2	**bEndpointAddress**	1	Endpoint	The address of the endpoint on the USB device described by this descriptor. The address is encoded as follows: D7: Direction 0 = OUT endpoint 1 = IN endpoint D6..4: Reserved, reset to zero D3..0: The endpoint number, determined by the designer
3	**bmAttributes**	1	Bitmap	D1..0: Transfer type (set to 10 = Bulk) All other bits are reserved.
4	**wMaxPacketSize**	2	Number	Maximum packet size this endpoint is capable of sending or receiving when this configuration is selected.
6	**bInterval**	1	Number	Interval for polling endpoint for data transfers. This value is expressed as a period of frames or microframes depending on device speed.

3.10.2 VS Bulk Still Image Data Endpoint Descriptors

The standard bulk still image data endpoint descriptor provides pertinent information on how still image data are communicated to the video function. In addition, specific endpoint capabilities and properties are reported.

3.10.2.1 Standard VS Bulk Still Image Data Endpoint Descriptor

The standard VS Bulk still image data endpoint descriptor is identical to the standard endpoint descriptor defined in section 9.6.6 "Endpoint" of *USB Specification Revision 2.0*. D7 of the **bEndpointAddress** field indicates that this endpoint is a data source (D7 = 1). The **bmAttributes** field bits are set to reflect the bulk type of the endpoint.

This optional endpoint is only implemented by the device if it supports method 3 of still image capture. If implemented, it should always follow the Video Data endpoint (where available) in descriptor ordering and endpoint addressing.

Table 3-21 Standard VS Bulk Still Image Data Endpoint Descriptor

Offset	Field	Size	Value	Description
0	**bLength**	1	Number	Size of this descriptor, in bytes: 7
1	**bDescriptorType**	1	Constant	ENDPOINT descriptor type
2	**bEndpointAddress**	1	Endpoint	The address of the endpoint on the USB device described by this descriptor. The address is encoded as follows: D7: Direction (set to 1 = IN endpoint) D6..4: Reserved, reset to zero D3..0: The endpoint number, determined by the designer
3	**bmAttributes**	1	Bitmap	D1..0: Transfer type (set to 10 = Bulk) All other bits are reserved.
4	**wMaxPacketSize**	2	Number	Maximum packet size this endpoint is capable of sending or receiving when this configuration is selected.
6	**bInterval**	1	Number	Not used

3.11 String Descriptors

The baseline requirement for devices in this class is for the implementation of a function name string descriptor in US English (LANGID = 0x0409). This will be referenced in the **iInterface** field in the standard VideoControl interface descriptor. See section 3.7.1, "Standard VC Interface Descriptor".

If the VideoControl interface is part of a Video Interface Collection, the **iFunction** field in the IAD and the **iInterface** field in the Standard VC interface descriptor for this Video Interface Collection must be equal. See section 3.6, "Interface Association Descriptor".

All other string descriptors are optional.

Since the device must implement the device name string descriptor, it must also support String Descriptor Zero which contains the list of LANGID codes supported by the device. This descriptor, as well as the layout of a standard UNICODE String Descriptor, is defined in section 9.6.7 "String" of the *USB Specification Revision 2.0*.

4 Class-Specific Requests

Most class-specific requests are used to set and get video related Controls. These Controls fall into two main groups: those that manipulate controls related to the video function, such as brightness, exposure, selector position, etc. and those that influence data transfer over a video data endpoint, such as the current frame rate.

- VideoControl Requests. Control of a video function is performed through the manipulation of the attributes of individual Controls that are embedded in the Units and Terminals of the video function. The class-specific VideoControl interface descriptor contains a collection of Unit and Terminal descriptors, each indicating which Controls are present in each entity. VideoControl requests are always directed to the single VideoControl interface of the video function. The request contains enough information (Unit ID, Control Selector) for the video function to route a specific request correctly. The same request layout can be used for vendor-specific requests to Extension Units. However, they are not covered by this specification.
- VideoStreaming Requests. Control of the class-specific behavior of a VideoStreaming interface is performed through manipulation of either Interface Controls or Endpoint Controls. These can be either standard Controls, as defined in this specification or vendor-specific. In either case, the same request layout can be used. VideoStreaming requests are directed to either the interface where the Control resides.

Requests may be mandatory or optional and listed as such for every control. Where SET_CUR is optional its presence is determined via GET_INFO. If a video function does not support a certain request, it must indicate this by stalling the control pipe when that request is issued to the function.

4.1 Request Layout

The following paragraphs describe the general structure of the Set and Get requests. Subsequent paragraphs detail the use of the Set/Get requests for the different request types.

4.1.1 Set Request

This request is used to set an attribute of a Control inside an entity of the video function.

Table 4-1 Set Request

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00100001	SET_CUR	See following paragraphs.	Entity ID and Interface.	Length of parameter block.	Parameter block.
00100010			Endpoint.		

The **bmRequestType** field specifies that this is a SET request (D7=0). It is a class-specific request (D6..5=01), directed to either the VideoControl interface, or a VideoStreaming interface of the video function (D4..0=00001), or the video data endpoint of a VideoStreaming interface (D4..0=00010).

The **bRequest** field contains a constant that identifies which attribute of the addressed Control is to be modified. Possible attributes for a Control are:

- Current setting attribute (SET_CUR)

If the addressed Control or entity does not support modification of a certain attribute, the control pipe must indicate a stall when an attempt is made to modify that attribute. In most cases, only the CUR attribute will be supported for the Set request. However, this specification does not prevent a designer from making other attributes programmable. For the list of Request constants, refer to section A.8, "Video Class-Specific Request Codes"

The **wValue** field interpretation is qualified by the value in the **wIndex** field. Depending on what entity is addressed, the layout of the **wValue** field changes. The following paragraphs describe the contents of the **wValue** field for each entity separately. In most cases, the **wValue** field contains the Control Selector (CS) in the high byte. It is used to address a particular Control within entities that can contain multiple Controls. If the entity only contains a single Control, there is no need to specify a Control Selector and the **wValue** field can be used to pass additional parameters.

The **wIndex** field specifies the interface or endpoint to be addressed in the low byte, and the entity ID or zero in the high byte. In case an interface is addressed, the virtual entity "interface" can be addressed by specifying zero in the high byte. The values in **wIndex** must be appropriate to the recipient. Only existing entities in the video function can be addressed, and only appropriate interface or endpoint numbers may be used. If the request specifies an unknown or non-entity ID or an unknown interface or endpoint number, the control pipe must indicate a stall.

The actual parameter(s) for the Set request are passed in the data stage of the control transfer. The length of the parameter block is indicated in the **wLength** field of the request. The layout of the parameter block is qualified by both the **bRequest** and **wIndex** fields. Refer to the following sections for a detailed description of the parameter block layout for all possible entities.

4.1.2 Get Request

This request returns the attribute setting of a specific Control inside an entity of the video function.

Table 4-2 Get Request

bmRequestType	bRequest	wValue	wIndex	wLength	Data
10100001	GET_CUR	See following	Entity ID and	Length of	Parameter

10100010	GET_MIN GET_MAX GET_RES GET_LEN GET_INFO GET_DEF	paragraphs.	Interface Endpoint.	parameter block	block

The **bmRequestType** field specifies that this is a GET request (D7=1). It is a class-specific request (D6..5=01), directed to either the VideoControl interface or a VideoStreaming interface of the video function (D4..0=00001), or the video data endpoint of a VideoStreaming interface (D4..0=00010).

The **bRequest** field contains a constant that identifies which attribute of the addressed Control or entity is to be returned. Possible attributes for a Control are:

- Current setting attribute (GET_CUR)
- Minimum setting attribute (GET_MIN)
- Maximum setting attribute (GET_MAX)
- Default setting attribute (GET_DEF)
- Resolution attribute (GET_RES)
- Data length attribute (GET_LEN)
- Information attribute (GET_INFO)

The GET_INFO request queries the capabilities and status of the specified control. When issuing this request, the **wLength** field shall always be set to a value of 1 byte. The result returned is a bit mask reporting the capabilities of the control. The bits are defined as:

Table 4-3 Defined Bits Containing Capabilities of the Control

Bit field	Description
D0	1=Supports GET value requests
D1	1=Supports SET value requests
D2	1=Disabled due to automatic mode (under device control)
D3	1= Autoupdate Control (see section 2.4.2.2 "Status Interrupt Endpoint")
D4	1= Asynchronous Control (see sections 2.4.2.2 "Status Interrupt Endpoint" and 2.4.4, “Control Transfer and Request Processing”)
D7..D5	Reserved (Set to 0)

The device indicates hardware default values for Unit, Terminal and Interface Controls through their GET_DEF values. These values may be used by the host to restore a control to its default setting.

If the addressed Control or entity does not support readout of a certain attribute, the control pipe must indicate a stall when an attempt is made to read that attribute. For the list of Request constants, refer to section A.8, "Video Class-Specific Request Codes".

The **wValue** field interpretation is qualified by the value in the **wIndex** field. Depending on what entity is addressed, the layout of the **wValue** field changes. The following paragraphs describe the contents of the **wValue** field for each entity separately. In most cases, the **wValue** field contains the Control Selector (CS) in the high byte. It is used to address a particular Control within entities that can contain multiple Controls. If the entity only contains a single Control, there is no need to specify a Control Selector and the **wValue** field can be used to pass additional parameters.

The **wIndex** field specifies the interface or endpoint to be addressed in the low byte, and the entity ID or zero in the high byte. In case an interface is addressed, the virtual entity "interface" can be addressed by specifying zero in the high byte. The values in **wIndex** must be appropriate to the recipient. Only existing entities in the video function can be addressed, and only appropriate interface or endpoint numbers may be used. If the request specifies an unknown or non-entity ID, or an unknown interface or endpoint number, the control pipe must indicate a stall.

The actual parameter(s) for the Get request are returned in the data stage of the control transfer. The length of the parameter block to return is indicated in the **wLength** field of the request. If the parameter block is longer than is indicated in the **wLength** field, only the initial bytes of the parameter block are returned. If the parameter block is shorter than is indicated in the **wLength** field, the device indicates the end of the control transfer by sending a short packet when further data is requested. The layout of the parameter block is qualified by both the **bRequest** and **wIndex** fields. Refer to the following sections for a detailed description of the parameter block layout for all possible entities.

4.2 VideoControl Requests

The following sections describe the possible requests that can be used to manipulate the video Controls a video function exposes through its VideoControl interface and Units contained within it. The same layout of the parameter blocks is used for both the Set and Get requests.

4.2.1 Interface Control Requests

These requests are used to set or read an attribute of an interface Control inside the VideoControl interface of the video function.

Table 4-4 Interface Control Requests

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00100001	SET_CUR	CS	Zero and Interface.	Length of parameter block.	Parameter block.
10100001	GET_CUR GET_MIN GET_MAX				

	GET_RES GET_INFO				

The **bRequest** field indicates which attribute the request is manipulating. The MIN, MAX, and RES attributes are usually not supported for the Set request.

The **wValue** field specifies the Control Selector (CS) in the high byte, and the low byte must be set to zero. The Control Selector indicates which type of Control this request is manipulating. If the request specifies an unknown CS to that endpoint, the control pipe must indicate a stall.

4.2.1.1 Power Mode Control

This control sets the device power mode. Power modes are defined in the following table.

Table 4-5 Power Mode Control

Device power mode	Description
Full power mode	Device operates at full functionality in this mode. For example, the device can stream video data via USB, and can execute all requests that are supported by the device. This mode is mandated, even if the device doesn't support VIDEO POWER MODE CONTROL.
Vendor-dependent power mode	Device operates in low power mode. In this mode, the function of the USB Video Class continues to work, although the device is not operating at full functionality. For example, as the result of setting the device to this power mode, the device will stop the Zoom function. To avoid confusing the user, the device should issue an interrupt (GET_INFO) to notify the user that the Zoom function is disabled. In this mode, the device can stream video data, the functionality of USB is not affected, and the device can execute all requests that it supports. This mode is optional.

The power mode that is supported by the device must be passed to the host, as well as the power source, since if the device is working with battery power, the host can change the device power mode to "vendor-dependent power mode" to reduce power consumption.
Information regarding power modes and power sources is communicated through the following bit fields. D7..D5 indicates which power source is currently used in the device. The D4 indicates that the device supports "vendor-dependent power mode". Bits D7..D4 are set by the device and is read-only. The host can change the device power mode by setting a combination of D3..D0.

The host can update the power mode during video streaming.

The D3..D0 value of 0000B indicates that the device is in, or should transition to, full power mode. The D3..D0 value of 0001B indicates that the device is in, or should transition to, vendor-dependent power mode.
The host must specify D3..D0 only when the power mode is required to switch, and the other fields must be set to 0.

Table 4-6 Device Power Mode

Control selector		VC_VIDEO_POWER_MODE_CONTROL					
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO					
wLength		1					
Offset	Field	Size	Value	Description			
0	**bDevicePowerMode**	1	Bitmap				
				Bit	Description	R	W
				D3..0	Power Mode setting 0000B:Full power mode 0001B:device dependent power mode (opt.) All other bits are reserved.	o	o
				D4	Device dependent power mode supported.	o	x
				D5	Device uses power supplied by USB.	o	x
				D6	Device uses power supplied by Battery.	o	x
				D7	Device uses power supplied by A.C.	o	x

4.2.1.2 Request Error Code Control

This read-only control indicates the status of each host-initiated request to a Terminal, Unit, interface or endpoint of the video function. If the device is unable to fulfill the request, it will indicate a stall on the control pipe and update this control with the appropriate code to indicate the cause. This control will be reset to 0 (No error) upon the successful completion of any control request (including requests to this control). Asynchronous control requests are a special case, where the initial request will update this control, but the final result is delivered via the Status Interrupt Endpoint (see sections 2.4.2.2, "Status Interrupt Endpoint" and 2.4.4, "Control Transfer and Request Processing").

Table 4-7 Request Error Code Control

Control Selector		VC_REQUEST_ERROR_CODE_CONTROL		
Mandatory Requests		GET_CUR, GET_INFO		
wLength		1		
Offset	Field	Size	Value	Description

0	**bRequestErrorCode**	1	Number	0x00: No error 0x01: Not ready 0x02: Wrong state 0x03: Power 0x04: Out of range 0x05: Invalid unit 0x06: Invalid control 0x07: Invalid Request 0x08-0xFE: Reserved for future use 0xFF: Unknown

4.2.1.3 Indicate Host Clock Control

This control indicates the host master clock nominal frequency to a device. This control is mandatory for devices supporting host to device payloads requiring SCR/PTS.
This control shall be initialized before any streaming operation is initiated. Attempts to change this control during streaming operation will STALL and the error code control will return the "Wrong State" error code.

Table 4-8 Indicate Host Clock Control

Control Selector		VC_REQUEST_INDICATE_HOST_CLOCK_CONTROL		
Mandatory Requests		GET_CUR, SET_CUR		
wLength		4		
Offset	Field	Size	Value	Description
0	**dwHostClockFreq**	4	Number	Clock frequency in [Hz] Specifies the host master clock nominal frequency. The device uses this value for clock recovery.

4.2.2 Unit and Terminal Control Requests

These requests are used to set or read an attribute of a Terminal Control inside a Terminal of the video function.

Table 4-9 Unit and Terminal Control Requests

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00100001	SET_CUR	CS	Unit or Terminal ID and Interface	Length of parameter block	Parameter block
10100001	GET_CUR GET_MIN GET_MAX GET_RES GET_INFO GET_DEF				

The **bRequest** field indicates which attribute the request is manipulating. The MIN, MAX and RES attributes are usually not supported for the Set request.

The **wValue** field specifies the Control Selector (CS) in the high byte, and zero in the low byte. The Control Selector indicates which type of Control this request is manipulating. If the request specifies an unknown or unsupported CS to that Unit or Terminal, the control pipe must indicate a stall.

There are special Terminal types (such as the Camera Terminal and Media Transport Terminal) that have type-specific Terminal Controls defined. The controls for the Media Transport Terminal are defined in a companion specification (see the *USB Device Class Definition for Video Media Transport Terminal* specification). The controls for the Camera Terminal are defined in the following sections.

4.2.2.1 Camera Terminal Control Requests

The following paragraphs present a detailed description of all possible Controls a Camera Terminal can incorporate. For each Control, the layout of the parameter block together with the appropriate Control Selector is listed for all forms of the Get/Set Camera Terminal Control request. All values are interpreted as absolute (fixed-origin), and not relative unless otherwise specified. They are also assumed to be unsigned unless otherwise specified.

4.2.2.1.1 Scanning Mode Control

The Scanning Mode Control setting is used to control the scanning mode of the camera sensor. A value of 0 indicates that the interlace mode is enabled, and a value of 1 indicates that the progressive or the non-interlace mode is enabled.

Table 4-10 Scanning Mode Control

Control Selector		CT_SCANNING_MODE_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO		
wLength		1		
Offset	Field	Size	Value	Description
0	**bScanningMode**	1	Boolean	The setting for the attribute of the addressed Scanning Mode Control: 0: Interlaced 1: Progressive

4.2.2.1.2 Auto-Exposure Mode Control

The Auto-Exposure Mode Control determines whether the device will provide automatic adjustment of the Exposure Time and Iris controls. Attempts to programmatically set the auto-adjusted controls are then ignored. A GET_RES request issued to this control will return a bitmap of the modes supported by this control. A valid request to this control would have only one bit set (a single mode selected). This control must accept the GET_DEF request and return its default value.

Table 4-11 Auto-Exposure Mode Control

Control Selector		CT_AE_MODE_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_RES, GET_INFO, GET_DEF		
wLength		1		
Offset	Field	Size	Value	Description
0	**bAutoExposureMode**	1	Bitmap	The setting for the attribute of the addressed Auto-Exposure Mode Control: D0: Manual Mode – manual Exposure Time, manual Iris D1: Auto Mode – auto Exposure Time, auto Iris D2: Shutter Priority Mode – manual Exposure Time, auto Iris D3: Aperture Priority Mode – auto Exposure Time, manual Iris

4.2.2.1.3 Auto-Exposure Priority Control

The Auto-Exposure Priority Control is used to specify constraints on the Exposure Time Control when the Auto-Exposure Mode Control is set to Auto Mode or Shutter Priority Mode. A value of zero indicates that the frame rate must remain constant. A value of 1 indicates that the frame rate may be dynamically varied by the device. The default value is zero (0).

Table 4-12 Auto-Exposure Priority Control

Control Selector		CT_AE_PRIORITY_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO		
wLength		1		
Offset	Field	Size	Value	Description
0	**bAutoExposurePriority**	1	Number	The setting for the attribute of the addressed AutoExposure Priority control.

4.2.2.1.4 Exposure Time (Absolute) Control

The Exposure Time (Absolute) Control is used to specify the length of exposure. This value is expressed in 100us units, where 1 is 1/10,000th of a second, 10,000 is 1 second, and 100,000 is 10 seconds. A value of zero (0) is undefined. Note that the manual exposure control is further limited by the frame interval, which always has higher precedence. If the frame interval is changed to a value below the current value of the Exposure Control, the Exposure Control value will automatically be changed. The default Exposure Control value will be the current frame interval until an explicit exposure value is chosen. This control will not accept SET requests when the Auto-Exposure Mode control is in Auto mode or Aperture Priority mode, and the control pipe shall indicate a stall in this case. This control must accept the GET_DEF request and return its default value.

Table 4-13 Exposure Time (Absolute) Control

Control Selector		CT_EXPOSURE_TIME_ABSOLUTE_CONTROL		
Mandatory Requests		GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
Optional Requests		SET_CUR		
wLength		4		
Offset	Field	Size	Value	Description
0	**dwExposureTimeAbsolute**	4	Number	The setting for the attribute of the addressed Exposure Time (Absolute) Control: 0: Reserved 1: 0.0001 sec … 100000: 10 sec …

4.2.2.1.5 Exposure Time (Relative) Control

The Exposure Time (Relative) Control is used to specify the electronic shutter speed. This value is expressed in number of steps of exposure time that is incremented or decremented. A value of one (1) indicates that the exposure time is incremented one step further, and a value 0xFF indicates that the exposure time is decremented one step further. This step is implementation specific. A value of zero (0) indicates that the exposure time is set to the default value for implementation. The default values are implementation specific. This control will not accept SET requests when the Auto-Exposure Mode control is in Auto mode or Aperture Priority mode, and the control pipe shall indicate a stall in this case.

Table 4-14 Exposure Time (Relative) Control

Control Selector	CT_EXPOSURE_TIME_RELATIVE_CONTROL

Mandatory Requests		SET_CUR, GET_CUR, GET_INFO		
wLength		1		
Offset	Field	Size	Value	Description
0	**bExposureTimeRelative**	1	Signed Number	The setting for the attribute of the addressed Exposure Time (Relative) Control: 0: default 1: incremented by 1 step 0xFF: decremented by 1 step

4.2.2.1.6 Focus (Absolute) Control

The Focus (Absolute) Control is used to specify the distance to the optimally focused target. This value is expressed in millimeters. The default value is implementation-specific. This control must accept the GET_DEF request and return its default value.

Table 4-15 Focus (Absolute) Control

Control Selector		CT_FOCUS_ABSOLUTE_CONTROL		
Mandatory Requests		GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
Optional Requests		SET_CUR		
wLength		2		
Offset	Field	Size	Value	Description
0	**wFocusAbsolute**	2	Number	The setting for the attribute of the addressed Focus (Absolute) Control.

4.2.2.1.7 Focus (Relative) Control

The Focus (Relative) Control is used to move the focus lens group to specify the distance to the optimally focused target.
The **bFocusRelative** field indicates whether the focus lens group is stopped or is moving for near or is moving for infinity direction. A value of 1 indicates that the focus lens group is moved for near direction. A value of 0 indicates that the focus lens group is stopped. And a value of 0xFF indicates that the lens group is moved for infinity direction. The GET_MIN, GET_MAX, GET_RES and GET_DEF requests will return zero for this field.

The **bSpeed** field indicates the speed of the lens group movement. A low number indicates a slow speed and a high number indicates a high speed.
The GET_MIN, GET_MAX and GET_RES requests are used to retrieve the range and resolution for this field. The GET_DEF request is used to retrieve the default value for this field. If the control does not support speed control, it will return the value 1 in this field for all these requests.

Table 4-16 Focus (Relative) Control

Control Selector		CT_FOCUS_RELATIVE_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO, GET_DEF, GET_MIN, GET_MAX, GET_RES		
wLength		2		
Offset	Field	Size	Value	Description
0	**bFocusRelative**	1	Signed number	The setting for the attribute of the addressed Focus (Relative) Control: 0: Stop 1: Focus Near direction 0xFF: Focus Infinite direction
1	**bSpeed**	1	Number	Speed for the control change

4.2.2.1.8 Focus, Auto Control

The Focus, Auto Control setting determines whether the device will provide automatic adjustment of the Focus Absolute or Relative Controls. A value of 1 indicates that automatic adjustment is enabled. Attempts to programmatically set the related controls are then ignored. This control must accept the GET_DEF request and return its default value.

Table 4-17 Focus, Auto Control

Control Selector		CT_FOCUS_AUTO_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO, GET_DEF		
wLength		1		
Offset	Field	Size	Value	Description
0	**bFocusAuto**	1	Boolean	The setting for the attribute of the addressed Focus Auto control.

4.2.2.1.9 Iris (Absolute) Control

The Iris (Absolute) Control is used to specify the camera's aperture setting. This value is expressed in units of f_{stop} * 100. The default value is implementation-specific.
This control will not accept SET requests when the Auto-Exposure Mode control is in Auto mode or Shutter Priority mode, and the control pipe shall indicate a stall in this case. This control must accept the GET_DEF request and return its default value.

Table 4-18 Iris (Absolute) Control

Control Selector	CT_IRIS_ABSOLUTE_CONTROL
Mandatory Requests	GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF
Optional Requests	SET_CUR
wLength	2

Offset	Field	Size	Value	Description
0	**wIrisAbsolute**	2	Number	The setting for the attribute of the addressed Iris (Absolute) Control.

4.2.2.1.10 Iris (Relative) Control

The Iris (Relative) Control is used to specify the camera's aperture setting. This value is a signed integer and indicates the number of steps to open or close the iris. A value of 1 indicates that the iris is opened 1 step further. A value of 0xFF indicates that the iris is closed 1 step further. This step of iris is implementation specific. A value of zero (0) indicates that the iris is set to the default value for the implementation. The default value is implementation specific. This control will not accept SET requests when the Auto-Exposure Mode control is in Auto mode or Shutter Priority mode, and the control pipe shall indicate a stall in this case.

Table 4-19 Iris (Relative) Control

Control Selector		CT_IRIS_RELATIVE_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO		
wLength		1		
Offset	Field	Size	Value	Description
0	**bIrisRelative**	1	Number	The setting for the attribute of the addressed Iris (Relative) Control: 0: Default 1: Iris is opened by 1 step. 0xFF: Iris is closed by 1 step.

4.2.2.1.11 Zoom (Absolute) Control

The Zoom (Absolute) Control is used to specify or determine the Objective lens focal length. This control is used in combination with the **wObjectiveFocalLengthMin** and **wObjectiveFocalLengthMax** fields in the Camera Terminal descriptor to describe and control the Objective lens focal length of the device (see section 2.4.2.5.1 "Optical Zoom"). The MIN and MAX values are sufficient to imply the resolution, so the RES value must always be 1. The MIN, MAX and default values are implementation dependent. This control must accept the GET_DEF request and return its default value.

Table 4-20 Zoom (Absolute) Control

Control Selector		CT_ZOOM_ABSOLUTE_CONTROL		
Mandatory Requests		GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
Optional Requests		SET_CUR		
wLength		2		
Offset	Field	Size	Value	Description

0	**wObjectiveFocalLength**	2	Number	The value of Z_{cur} (see section 2.4.2.5.1 "Optical Zoom".)

4.2.2.1.12 Zoom (Relative) Control

The Zoom (Relative) Control is used to specify the zoom focal length relatively as powered zoom.

The **bZoom** field indicates whether the zoom lens group is stopped or the direction of the zoom lens. A value of 1 indicates that the zoom lens is moved towards the telephoto direction. A value of zero indicates that the zoom lens is stopped, and a value of 0xFF indicates that the zoom lens is moved towards the wide-angle direction. The GET_MIN, GET_MAX, GET_RES and GET_DEF requests will return zero for this field.

The **bDigitalZoom** field specifies whether digital zoom is enabled or disabled. If the device only supports digital zoom, this field would be ignored. The GET_DEF request will return the default value for this field. The GET_MIN, GET_MAX and GET_RES requests will return zero for this field.

The **bSpeed** field indicates the speed of the control change. A low number indicates a slow speed and a high number indicates a higher speed.
The GET_MIN, GET_MAX and GET_RES requests are used to retrieve the range and resolution for this field. The GET_DEF request is used to retrieve the default value for this field. If the control does not support speed control, it will return the value 1 in this field for all these requests.

Table 4-21 Zoom (Relative) Control

Control Selector		CT_ZOOM_RELATIVE_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO, GET_DEF, GET_MIN, GET_MAX, GET_RES		
wLength		3		
Offset	Field	Size	Value	Description
0	**bZoom**	1	Signed number	The setting for the attribute of the addressed Zoom Control: 0: Stop 1: moving to telephoto direction 0xFF: moving to wide-angle direction
1	**bDigitalZoom**	1	Boolean	0: Digital Zoom OFF 1: Digital Zoom On
2	**bSpeed**	1	Number	Speed for the control change

4.2.2.1.13 PanTilt (Absolute) Control

The PanTilt (Absolute) Control is used to specify the pan and tilt settings.

The d**wPanAbsolute** is used to specify the pan setting in arc second units. 1 arc second is 1/3600 of a degree. Values range from –180*3600 arc second to +180*3600 arc second, or a subset thereof, with the default set to zero. Positive values are clockwise from the origin (the camera rotates clockwise when viewed from above), and negative values are counterclockwise from the origin. This control must accept the GET_DEF request and return its default value.

The **dwTiltAbsolute** Control is used to specify the tilt setting in arc second units. 1 arc second is 1/3600 of a degree. Values range from –180*3600 arc second to +180*3600 arc second, or a subset thereof, with the default set to zero. Positive values point the imaging plane up, and negative values point the imaging plane down. This control must accept the GET_DEF request and return its default value.

Table 4-22 PanTilt (Absolute) Control

Control Selector		CT_PANTILT_ABSOLUTE_CONTROL		
Mandatory Requests		GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
Optional Requests		SET_CUR		
wLength		8		
Offset	Field	Size	Value	Description
0	**dwPanAbsolute**	4	Signed number	The setting for the attribute of the addressed Pan (Absolute) Control.
4	**dwTiltAbsolute**	4	Signed number	The setting for the attribute of the addressed Tilt (Absolute) Control.

4.2.2.1.14 PanTilt (Relative) Control

The PanTilt (Relative) Control is used to specify the pan and tilt direction to move.

The **bPanRelative** is used to specify the pan direction to move. A value of 0 indicates to stop the pan, a value of 1 indicates to start moving clockwise direction, and a value of 0xFF indicates to start moving counterclockwise direction. The GET_DEF, GET_MIN, GET_MAX and GET_RES requests will return zero for this field.

The **bPanSpeed** field is used to specify the speed of the movement for the Pan direction. A low number indicates a slow speed and a high number indicates a higher speed.
The GET_MIN, GET_MAX and GET_RES requests are used to retrieve the range and resolution for this field. The GET_DEF request is used to retrieve the default value for this field. If the control does not support speed control for the Pan control, it will return the value 1 in this field for all these requests.

The **bTiltRelative** is used to specify the tilt direction to move. A value of zero indicates to stop the tilt, a value of 1 indicates that the camera point the imaging plane up, and a value of 0xFF indicates that the camera point the imaging plane down. The GET_DEF, GET_MIN, GET_MAX and GET_RES requests will return zero for this field.

The **bTiltSpeed** field is used to specify the speed of the movement for the Tilt direction. A low number indicates a slow speed and a high number indicates a higher speed.
The GET_MIN, GET_MAX and GET_RES requests are used to retrieve the range and resolution for this field. The GET_DEF request is used to retrieve the default value for this field. If the control does not support speed control for the Tilt control, it will return the value 1 in this field for all these requests.

Table 4-23 PanTilt (Relative) Control

Control Selector		CT_PANTILT_RELATIVE_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO, GET_DEF, GET_MIN, GET_MAX, GET_RES		
wLength		4		
Offset	Field	Size	Value	Description
0	**bPanRelative**	1	Signed number	The setting for the attribute of the addressed Pan (Relative) Control: 0: Stop 1: moving to clockwise direction 0xFF: moving to counter clockwise direction
1	**bPanSpeed**	1	Number	Speed of the Pan movement
2	**bTiltRelative**	1	Signed number	The setting for the attribute of the addressed Tilt (Relative) Control: 0: Stop 1: point the imaging plane up 0xFF: point the imaging plane down
3	**bTiltSpeed**	1	Number	Speed for the Tilt movement

4.2.2.1.15 Roll (Absolute) Control

The Roll (Absolute) Control is used to specify the roll setting in degrees. Values range from –180 to +180, or a subset thereof, with the default being set to zero. Positive values cause a clockwise rotation of the camera along the image viewing axis, and negative values cause a counterclockwise rotation of the camera. This control must accept the GET_DEF request and return its default value.

Table 4-24 Roll (Absolute) Control

Control Selector	CT_ROLL_ABSOLUTE_CONTROL

Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wRollAbsolute**	2	Signed number	The setting for the attribute of the addressed Roll (Absolute) Control.

4.2.2.1.16 Roll (Relative) Control

The Roll (Relative) Control is used to specify the roll direction to move.

The **bRollRelative** field is used to specify the roll direction to move. A value of 0 indicates to stop the roll, a value of 1 indicates to start moving in a clockwise rotation of the camera along the image viewing axis, and a value of 0xFF indicates to start moving in a counterclockwise direction. The GET_DEF, GET_MIN, GET_MAX and GET_RES requests will return zero for this field.

The **bSpeed** is used to specify the speed of the roll movement. A low number indicates a slow speed and a high number indicates a higher speed.

The GET_MIN, GET_MAX and GET_RES requests are used to retrieve the range and resolution for this field. The GET_DEF request is used to retrieve the default value for this field. If the control does not support speed control, it will return the value 1 in this field for all these requests.

Table 4-25 Roll (Relative) Control

Control Selector		CT_ROLL_RELATIVE_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO, GET_DEF, GET_MIN, GET_MAX, GET_RES		
wLength		2		
Offset	Field	Size	Value	Description
0	**bRollRelative**	1	Signed number	The setting for the attribute of the addressed Roll (Relative) Control: 0: Stop 1: moving clockwise rotation 0xFF: moving counter clockwise rotation
1	**bSpeed**	1	Number	Speed for the Roll movement

4.2.2.1.17 Privacy Control

The Privacy Control setting is used to prevent video from being acquired by the camera sensor. A value of 0 indicates that the camera sensor is able to capture video images, and a value of 1 indicates that the camera sensor is prevented from capturing video images.
This control shall be reported as an AutoUpdate control.

Table 4-26 Privacy Shutter Control

Control Selector		CT_PRIVACY_CONTROL		
Mandatory Requests		GET_CUR, GET_INFO		
Optional Requests		SET_CUR		
wLength		1		
Offset	Field	Size	Value	Description
0	**bPrivacy**	1	Boolean	The setting for the attribute of the addressed Privacy Control: 0: Open 1: Close

4.2.2.2 Selector Unit Control Requests

These requests are used to set or read an attribute of a Selector Control inside a Selector Unit of the video function.

A Selector Unit represents a video stream source selector. The valid range for the CUR, MIN, and MAX attributes is from one up to the number of Input Pins of the Selector Unit. This value can be found in the **bNrInPins** field of the Selector Unit descriptor. The RES attribute can only have a value of one. The Selector Control honors the request to the best of its abilities. It may round the **bSelector** attribute value to its closest available setting. It will report this rounded setting when queried during a Get Selector Unit Control request.

Table 4-27 Selector Unit Control Requests

Control Selector		SU_INPUT_SELECT_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_INFO		
wLength		1		
Offset	Field	Size	Value	Description
0	**bSelector**	1	Number	The setting for the attribute of the Selector Control.

4.2.2.3 Processing Unit Control Requests

These requests are used to set or read an attribute of a video Control inside a Processing Unit of the video function.

The following paragraphs present a detailed description of all possible Controls a Processing Unit can incorporate. For each Control, the layout of the parameter block together with the appropriate Control Selector is listed for all forms of the Get/Set Processing Unit Control request. All values are interpreted as unsigned unless otherwise specified.

4.2.2.3.1 Backlight Compensation Control

The Backlight Compensation Control is used to specify the backlight compensation. A value of zero indicates that the backlight compensation is disabled. A non-zero value indicates that the backlight compensation is enabled. The device may support a range of values, or simply a binary switch. If a range is supported, a low number indicates the least amount of backlight compensation. The default value is implementation-specific, but enabling backlight compensation is recommended. This control must accept the GET_DEF request and return its default value.

Table 4-28 Backlight Compensation Control

Control Selector		PU_BACKLIGHT_COMPENSATION_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wBacklightCompensation**	2	Number	The setting for the attribute of the addressed Backlight Compensation control.

4.2.2.3.2 Brightness Control

This is used to specify the brightness. This is a relative value where increasing values indicate increasing brightness. The MIN and MAX values are sufficient to imply the resolution, so the RES value must always be 1. The MIN, MAX and default values are implementation dependent. This control must accept the GET_DEF request and return its default value.

Table 4-29 Brightness Control

Control Selector		PU_BRIGHTNESS_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wBrightness**	2	Signed number	The setting for the attribute of the addressed Brightness control.

4.2.2.3.3 Contrast Control

This is used to specify the contrast value. This is a relative value where increasing values indicate increasing contrast. The MIN and MAX values are sufficient to imply the resolution, so the RES value must always be 1. The MIN, MAX and default values are implementation dependent. This control must accept the GET_DEF request and return its default value.

Table 4-30 Contrast Control

Control Selector		PU_CONTRAST_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wContrast**	2	Number	The setting for the attribute of the addressed Contrast control.

4.2.2.3.4 Gain Control

This is used to specify the gain setting. This is a relative value where increasing values indicate increasing gain. The MIN and MAX values are sufficient to imply the resolution, so the RES value must always be 1. The MIN, MAX and default values are implementation dependent. This control must accept the GET_DEF request and return its default value.

Table 4-31 Gain Control

Control Selector		PU_GAIN_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wGain**	2	Number	The setting for the attribute of the addressed Gain control.

4.2.2.3.5 Power Line Frequency Control

This control allows the host software to specify the local power line frequency, in order for the device to properly implement anti-flicker processing, if supported. The default is implementation-specific. This control must accept the GET_DEF request and return its default value.

Table 4-32 Power Line Frequency Control

Control Selector		PU_POWER_LINE_FREQUENCY_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO, GET_DEF		
wLength		1		
Offset	Field	Size	Value	Description

0	**bPowerLineFrequency**	1	Number	The setting for the attribute of the addressed Power Line Frequency control: 0: Disabled 1: 50 Hz 2: 60 Hz

4.2.2.3.6 Hue Control

This is used to specify the hue setting. The value of the hue setting is expressed in degrees multiplied by 100. The required range must be a subset of -18000 to 18000 (-180 to +180 degrees). The default value must be zero. This control must accept the GET_DEF request and return its default value.

Table 4-33 Hue Control

Control Selector		PU_HUE_CONTROL		
Mandatory Requests		GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
Optional Requests		SET_CUR		
wLength		2		
Offset	Field	Size	Value	Description
0	**wHue**	2	Signed number	The setting for the attribute of the addressed Hue control.

4.2.2.3.7 Hue, Auto Control

The Hue, Auto Control setting determines whether the device will provide automatic adjustment of the related control. A value of 1 indicates that automatic adjustment is enabled. Attempts to programmatically set the related control are then ignored. This control must accept the GET_DEF request and return its default value.

Table 4-34 Hue, Auto Control

Control Selector		PU_HUE_AUTO_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO, GET_DEF		
wLength		1		
Offset	Field	Size	Value	Description
0	**bHueAuto**	1	Number	The setting for the attribute of the addressed Hue, Auto control.

4.2.2.3.8 Saturation Control

This is used to specify the saturation setting. This is a relative value where increasing values indicate increasing saturation. A Saturation value of 0 indicates grayscale. The MIN and MAX values are sufficient to imply the resolution, so the RES value must always be 1. The MIN, MAX and default values are implementation-dependent. This control must accept the GET_DEF request and return its default value.

Table 4-35 Saturation Control

Control Selector		PU_SATURATION_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wSaturation**	2	Number	The setting for the attribute of the addressed Saturation control.

4.2.2.3.9 Sharpness Control

This is used to specify the sharpness setting. This is a relative value where increasing values indicate increasing sharpness, and the MIN value always implies "no sharpness processing", where the device will not process the video image to sharpen edges. The MIN and MAX values are sufficient to imply the resolution, so the RES value must always be 1. The MIN, MAX and default values are implementation-dependent. This control must accept the GET_DEF request and return its default value.

Table 4-36 Sharpness Control

Control Selector		PU_SHARPNESS_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wSharpness**	2	Number	The setting for the attribute of the addressed Sharpness control.

4.2.2.3.10 Gamma Control

This is used to specify the gamma setting. The value of the gamma setting is expressed in gamma multiplied by 100. The required range must be a subset of 1 to 500, and the default values are typically 100 (gamma = 1) or 220 (gamma = 2.2). This control must accept the GET_DEF request and return its default value.

Table 4-37 Gamma Control

Control Selector		PU_GAMMA_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wGamma**	2	Number	The setting for the attribute of the addressed Gamma control.

4.2.2.3.11 White Balance Temperature Control

This is used to specify the white balance setting as a color temperature in degrees Kelvin. This is offered as an alternative to the White Balance Component control. Minimum range should be 2800 (incandescent) to 6500 (daylight) for webcams and dual-mode cameras. The supported range and default value for white balance temperature is implementation-dependent. This control must accept the GET_DEF request and return its default value.

Table 4-38 White Balance Temperature Control

Control Selector		PU_WHITE_BALANCE_TEMPERATURE_CONTROL		
Mandatory Requests		GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
Optional Requests		SET_CUR		
wLength		2		
Offset	Field	Size	Value	Description
0	**wWhiteBalanceTemperature**	2	Number	The setting for the attribute of the addressed White Balance Temperature control.

4.2.2.3.12 White Balance Temperature, Auto Control

The White Balance Temperature, Auto Control setting determines whether the device will provide automatic adjustment of the related control. A value of 1 indicates that automatic adjustment is enabled. Attempts to programmatically set the related control are then ignored. This control must accept the GET_DEF request and return its default value.

Table 4-39 White Balance Temperature, Auto Control

Control Selector		PU_WHITE_BALANCE_TEMPERATURE_AUTO_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO, GET_DEF		
wLength		1		
Offset	Field	Size	Value	Description
0	**bWhiteBalanceTemperatureAuto**	1	Number	The setting for the attribute of the addressed White Balance Temperature, Auto control.

4.2.2.3.13 White Balance Component Control

This is used to specify the white balance setting as Blue and Red values for video formats. This is offered as an alternative to the White Balance Temperature control. The supported range and default value for white balance components is implementation-dependent. The device shall interpret the controls as blue and red pairs. This control must accept the GET_DEF request and return its default value.

Table 4-40 White Balance Component Control

Control Selector		PU_WHITE_BALANCE_COMPONENT_CONTROL		
Mandatory Requests		GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
Optional Requests		SET_CUR		
wLength		4		
Offset	Field	Size	Value	Description
0	**wWhiteBalanceBlue**	2	Number	The setting for the blue component of the addressed White Balance Component control.
1	**wWhiteBalanceRed**	2	Number	The setting for the red component of the addressed White Balance Component control.

4.2.2.3.14 White Balance Component, Auto Control

The White Balance Component, Auto Control setting determines whether the device will provide automatic adjustment of the related control. A value of 1 indicates that automatic adjustment is enabled. Attempts to programmatically set the related control are then ignored. This control must accept the GET_DEF request and return its default value.

Table 4-41 White Balance Component, Auto Control

Control Selector		PU_WHITE_BALANCE_COMPONENT_AUTO_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO, GET_DEF		
wLength		1		
Offset	Field	Size	Value	Description
0	**bWhiteBalanceComponentAuto**	1	Number	The setting for the attribute of the addressed White Balance Component, Auto control.

4.2.2.3.15 Digital Multiplier Control

This is used to specify the amount of Digital Zoom applied to the optical image. This is the position within the range of possible values of multiplier *m*, allowing the multiplier resolution to be described by the device implementation. The MIN and MAX values are sufficient to imply the resolution, so the RES value must always be 1. The MIN, MAX and default values are implementation dependent.

Table 4-42 Digital Multiplier Control

Control Selector		PU_DIGITAL_MULTIPLIER_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wMultiplierStep**	2	Number	The value Z'_{cur} (see section 2.4.2.5.2 "Digital Zoom".)

4.2.2.3.16 Digital Multiplier Limit Control

This is used to specify an upper limit for the amount of Digital Zoom applied to the optical image. This is the maximum position within the range of possible values of multiplier *m*. The MIN and MAX values are sufficient to imply the resolution, so the RES value must always be 1. The MIN, MAX and default values are implementation dependent.

Table 4-43 Digital Multiplier Limit Control

Control Selector		PU_DIGITAL_MULTIPLIER_LIMIT_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wMultiplierLimit**	2	Number	A value specifying the upper bound for Z'_{cur} (see section 2.4.2.5.2 "Digital Zoom".)

4.2.2.4 Extension Unit Control Requests

These requests are used to set or read a video Control inside a particular Extension Unit of the video function.

Because this specification receives no information about the inner workings of an Extension Unit, it is impossible to define requests that are able to manipulate vendor-specific Extension Unit Controls. However, this specification defines a number of standard Controls an Extension Unit can or must support.

Table 4-44 Extension Unit Control Requests

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00100001	SET_CUR	CS	Extension Unit ID and Interface	Length of parameter block	Parameter block
10100001	GET_CUR GET_MIN GET_MAX GET_RES GET_LEN GET_INFO				

The **bRequest** field indicates which attribute the request is manipulating. The MIN, MAX, and RES attributes are usually not supported for the Set request.

The **wValue** field specifies the Control Selector (CS) in the high byte and zero in the low byte. The Control Selector indicates which type of Control this request is manipulating. If the request specifies an unknown or unsupported CS to that Unit, the control pipe must indicate a stall. However, if the request specifies an available control, which may be vendor-specific, the request should succeed.

The range of CS values supported by the Extension Unit is dictated by the number of controls specified by the **bNumControls** field in the Extension Unit descriptor. See section 3.7.2.6, "Extension Unit Descriptor". The range should be [1..bNumControls].

The GET_LEN request queries for the length of the setting of the specified control. When issuing this request, the **wLength** field shall always be set to a value of 2 bytes. The result returned shall be the length specified for all attribute reads from the same control.

All vendor-specific controls supported by the Extension Unit must support the following requests:
GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF, GET_LEN.

The following request(s) are optional, depending on the control usage and behavior:
SET_CUR

4.2.2.4.1 Vendor-Defined Controls

All Extension Unit controls are vendor-defined. The vendor will have to provide the relevant host software to program these controls. The generic host driver will not have knowledge of the control details, but could act as a control transport between the vendor-provided host software and the device.

However, by using the GET_LEN request, the host driver would be able to query the length and raw data stored in the vendor-defined controls. While it would not be able to interpret this data, it would be capable of saving and restoring these control settings if required.

4.3 VideoStreaming Requests

VideoStreaming requests can be directed either to the VideoStreaming interface or to the associated video-data endpoint, depending on the location of the Control to be manipulated.

4.3.1 Interface Control Requests

These requests are used to set or read an attribute of an interface Control inside a particular VideoStreaming interface of the video function.

Table 4-45 Interface Control Requests inside a Particular VideoStreaming Interface

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00100001	SET_CUR	CS	Zero and Interface	Length of parameter block	Parameter block
10100001	GET_CUR GET_MIN GET_MAX GET_RES GET_DEF GET_LEN				

The **bRequest** field indicates which attribute the request is manipulating.

The **wValue** field specifies the Control Selector (CS) in the high byte, and the low byte must be set to zero. The CS indicates the type of Control that this request is manipulating. If the request specifies an unknown CS to that endpoint, the control pipe must indicate a stall.

The VideoStreaming interface controls allow the host software to query and set parameters related to the video stream format and the video stream encoder. These parameters include the format, frame size and frame rate of the video stream, as well as the format and frame size of still images captured by the device that are associated with the video stream. For devices that support host-adjustable video stream encoder parameters, controls allowing the adjustment of the key frame rate and compression quality, among other parameters, are also supported. Only Stream Error Code Control supports interrupt with VideoStreaming interface.

4.3.1.1 Video Probe and Commit Controls

The streaming parameters selection process is based on a shared negotiation model between the host and the video streaming interface taking into account the following features:

- shared nature of the USB
- interdependency of streaming parameters
- payload independence
- modification of streaming parameters during streaming

This negotiation model is supported by the Video Probe and Commit controls. The Probe control allows retrieval and negotiation of streaming parameters. When an acceptable combination of streaming parameters has been obtained, the Commit control provides the mean to setup the hardware with the negotiated parameters from the Probe control.

Table 4-46 Video Probe and Commit Controls

Control Selector		VS_PROBE_CONTROL VS_COMMIT_CONTROL		
Mandatory Requests		See tables below		
wLength		26		
Offset	Field	Size	Value	Description
0	**bmHint**	2	Bitmap	Bitfield control indicating to the function what parameters shall be kept fixed (indicative only): D0: dwFrameInterval D1: wKeyFrameRate D2: wPFrameRate D3: wCompQuality D4: wCompWindowSize D15..5: Reserved (0) The hint bitmap indicates to the video streaming interface which parameters shall be kept constant during stream parameters negotiation. For example, if the selection wants to favor frame rate over quality, the dwFrameInterval bit will be set (1). This parameter is set by the host, and is read-only for the video streaming interface.
2	**bFormatIndex**	1	Number	Video format index from a format descriptor. Select a specific video stream format by setting this field to the one-based index of the associated format descriptor. To select the first format defined by a device, a value one (1) is

				written to this field. This field must be supported even if only one video format is supported by the device.
3	**bFrameIndex**	1	Number	Video frame index from a frame descriptor. This field selects the video frame resolution from the array of resolutions supported by the selected stream. The index value ranges from 1 to the number of Frame descriptors following a particular Format descriptor. This field must be supported even if only one video frame index is supported by the device. For video payloads with no defined frame descriptor, this parameter shall be set to zero (0).
4	**dwFrameInterval**	4	Number	Frame interval in 100 ns units. This field sets the desired video frame interval for the selected video stream and frame index. The frame interval value is specified in 100 ns units. The device shall support the setting of all frame intervals reported in the Frame Descriptor corresponding to the selected Video Frame Index. This field must be implemented even if only one video frame interval is supported by the device. This field can be modified when the associated video pipe is active; the frame interval can be changed while streaming is occurring.
8	**wKeyFrameRate**	2	Number	Key frame rate in key frame/video frame units. This field is only supported by devices capable of streaming video with adjustable compression parameters, and support for this control is indicated in the VideoStreaming

				Header descriptor. The Key Frame Rate field is used to specify the compressor's key frame rate. For example, if one of every ten encoded frames in a video stream sequence is a key frame, this control would report a value of 10. A value of 0 indicates that only the first frame is a key frame.
10	**wPFrameRate**	2	Number	PFrame rate in PFrame/key frame units. This field is only supported by devices capable of streaming video with adjustable compression parameters, and support for this control is indicated in the VideoStreaming Header descriptor. The P Frame Rate Control is used to specify the number of P frames per key frame. As an example of the relationship between the types of encoded frames, suppose a key frame occurs once in every 10 frames, and there are 3 P frames per key frame. The P frames will be spaced evenly between the key frames. The other 6 frames, which occur between the key frames and the P frames, will be bi-directional (B) frames.
12	**wCompQuality**	2	Number	Compression quality control in abstract units 0 (lowest) to 10000 (highest). This field is only supported by devices capable of streaming video with adjustable compression parameters, and support for this field is indicated in the VideoStreaming Header descriptor.

				This field is used to specify the quality of the video compression. Values for this property range from 0 to 10000 (0 indicates the lowest quality, 10000 the highest). The resolution reported by this control will determine the number of discrete quality settings that it can support.
14	**wCompWindowSize**	2	Number	Window size for average bit rate control. This field is only supported by devices capable of streaming video with adjustable compression parameters; support for this control is indicated in the VideoStreaming Header descriptor. The Compression Window Size Control is used to specify the number of encoded video frames over which the average size cannot exceed the specified data rate. For a window of size *n*, the average frame size of any consecutive *n* frames will not exceed the stream's specified data rate. Individual frames can be larger or smaller. For example, if the data rate has been set to 100 kilobytes per second (KBps) on a 10 frames per second (fps) movie with a compression window size of 10, the individual frames can be any size, as long as the average size of a frame in any 10-frame sequence is less than or equal to 10 kilobytes.
16	**wDelay**	2	Number	Internal video streaming interface latency in ms from video data capture to presentation on the USB. This field indicates the internal video function delay. This latency represents the internal video function delay from

				the capture of data to its presentation on the USB. This parameter is set by the device and read only from the host.
18	**dwMaxVideoFrameSize**	4	Number	Maximum video frame size in bytes. This field indicates the maximum size of a single video frame. This value is only supported for frame-based payloads. This parameter is set by the device and read only from the host.
22	**dwMaxPayloadTransferSize**	4	Number	Specifies the maximum number of bytes that the device can transmit or receive in a single payload transfer.

4.3.1.1.1 Probe and Commit Operational Model

Unsupported fields shall be set to zero by the host and the device. Fields left for streaming parameters negotiation shall be set to zero by the host. For example, after a SET_CUR request initializing the FormatIndex and FrameIndex, the device will return the new negotiated field values for the supported fields when retrieving the Probe control GET_CUR attribute.
In order to avoid negotiation loops, the device shall always return streaming parameters with decreasing data rate requirements.
Unsupported streaming parameters shall be reset by the streaming interface to supported values according the negotiation loop avoidance rules. A side effect of this constraint is allowing the host to cycle through supported values of a field.

Negotiation rules should be applied on the following fields in order of decreasing priority:

- Format Index, FrameIndex and MaxPayloadTransferSize
- Streaming fields set to zero with their associated Hint bit set to 1
- All the remaining fields set to zero

The following table describes VS_PROBE_CONTROL request attributes.

Table 4-47 VS_PROBE_CONTROL Requests

Attribute	Description
GET_CUR	Returns the current state of the streaming interface. All supported fields set to zero will be returned with an acceptable negotiated value. After device configuration, this state undefined. This request shall stall

	in case of negotiation failure.
GET_MIN	Returns the minimum value for negotiated fields.
GET_MAX	Returns the maximum value for negotiated fields.
GET_RES	Return the resolution of each supported field in the Probe/Commit data structure.
GET_DEF	Returns the default value for the negotiated fields.
GET_LEN	Returns the length of the Probe data structure.
SET_CUR	Sets the streaming interface Probe state. This is the state used for stream parameters negotiations.

The following table describes VS_COMMIT_CONTROL request attributes.

Table 4-48 VS_COMMIT_CONTROL Requests

Attribute	Description
GET_CUR	Returns the current state of the streaming interface. After device configuration, this state undefined.
GET_MIN	Not supported.
GET_MAX	Not supported.
GET_RES	Not supported.
GET_DEF	Not supported.
GET_LEN	Returns the length of the Commit data structure.
SET_CUR	Sets the device state. This sets the active device state; the field values must be the result of a successful VS_PROBE_CONTROL(GET_CUR) request. This request shall stall in case an unsupported state is specified.

4.3.1.1.2 Stream Negotiation Examples

Successful USB isochronous bandwidth negotiation.

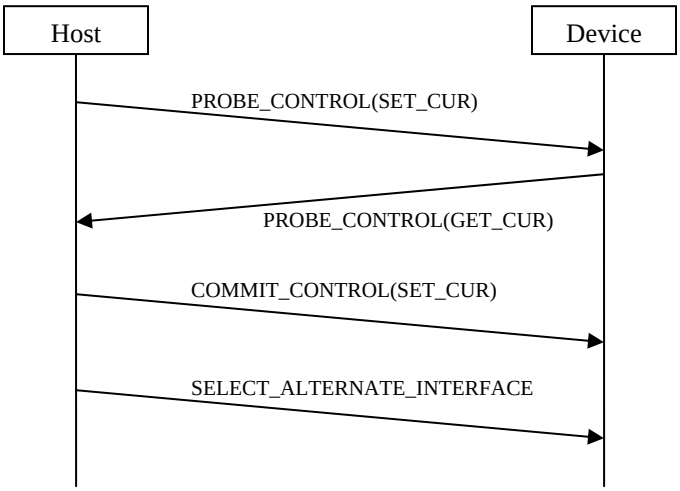

Figure 4-1 Successful USB Isochronous Bandwidth Negotiation

USB isochronous bandwidth negotiation failure.

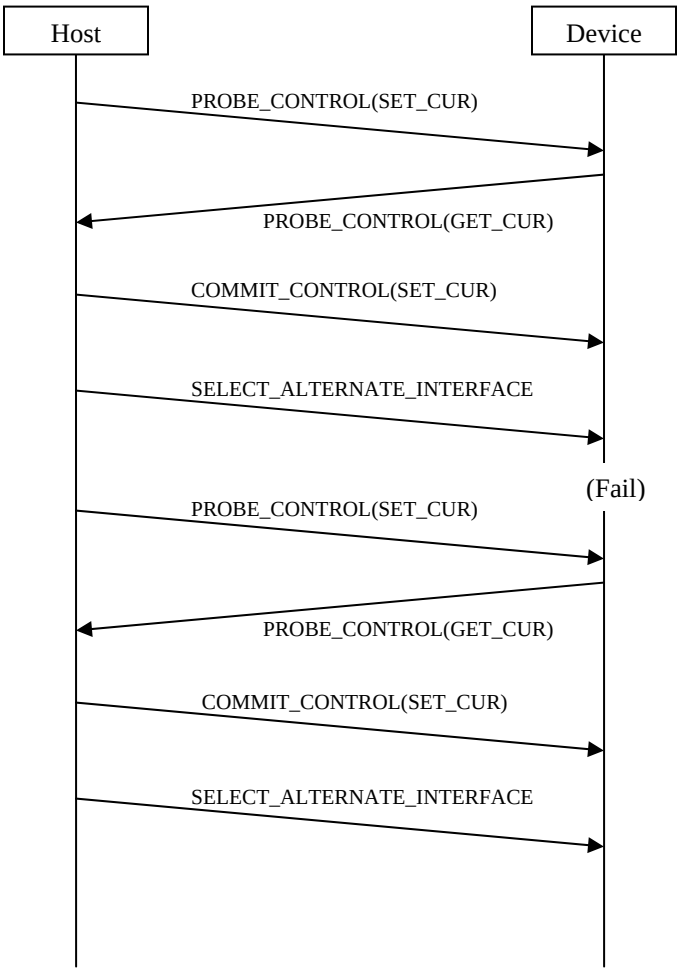

Figure 4-2 Failed USB Isochronous Bandwidth Negotiation

Dynamic stream settings modification while streaming.

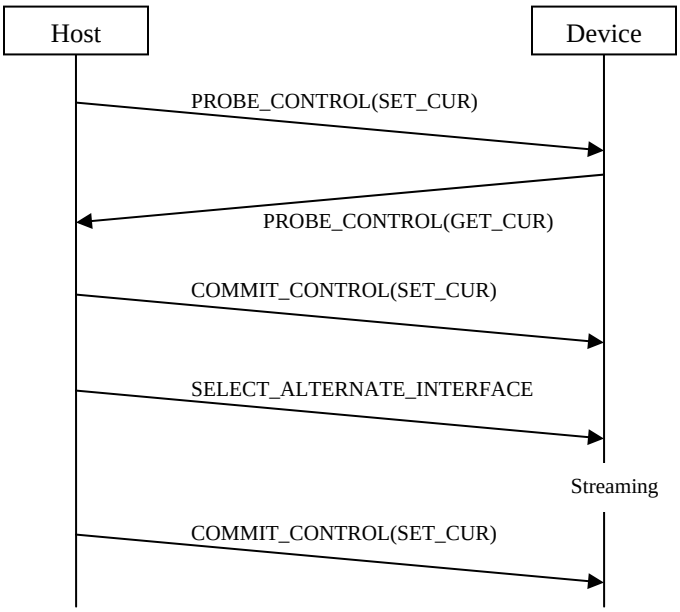

Figure 4-3 Dynamic Stream Settings Modification while Streaming

4.3.1.2 Video Still Probe Control and Still Commit Control

These still-image controls are required for video functions supporting method 2 or 3 for still-image retrieval.

Table 4-49 Video Still Probe Control and Still Commit Control

Control Selector		VS_STILL_PROBE_CONTROL VS_STILL_COMMIT_CONTROL		
Mandatory Requests		See tables below		
wLength		11		
Offset	Field	Size	Value	Description
0	**bFormatIndex**	1	Number	Video format index from a format descriptor. A specific still-image format is selected by setting this field to the one-based index for the associated format descriptor. To select the first format defined by a device, a value of 1 is written to this control.
1	**bFrameIndex**	1	Number	Video frame index from a frame descriptor. This field selects the still-image frame resolution from the array of resolutions supported by the selected still-image format. The index value ranges from one to the number of Still Image Size Patterns reported by the selected Still Image Frame descriptor.
2	**bCompressionIndex**	1	Number	Compression index from a frame descriptor. This field selects the still-image frame compression from the array of compression supported by the selected still-image format. The index value ranges from one to the number of Still Image Compression Patterns reported by the selected Still Image Frame descriptor.
3	**dwMaxVideoFrameSize**	4	Number	Maximum still image size in bytes. This field indicates the maximum size of a single still image. This parameter is set by the device and read only from the host.

7	**dwMaxPayloadTransferSize**	4	Number	Specifies the maximum number of bytes that the device can transmit or receive in a single payload transfer.

The following table describes VS_STILL_PROBE_CONTROL request attributes:

Table 4-50 VS_STILL_PROBE_CONTROL Requests

Attribute	Description
GET_CUR	Returns the current state of the device. After device configuration, this state undefined.
GET_MIN	Returns the minimum value for negotiated fields.
GET_MAX	Returns the maximum value for negotiated fields.
GET_RES	Not supported.
GET_DEF	Returns the default value for negotiated fields.
GET_LEN	Returns the length of the Probe data structure.
SET_CUR	Sets the streaming interface state. This is the state used for stream parameters negotiations.

The following table describes VS_STILL_COMMIT_CONTROL request attributes:

Table 4-51 VS_STILL_COMMIT_CONTROL Requests

Attribute	Description
GET_CUR	Returns the current state of the device. After device configuration, this state is undefined.
GET_MIN	Not supported.
GET_MAX	Not supported.
GET_RES	Not supported.
GET_DEF	Not supported.
GET_LEN	Returns the length of the Commit data structure.
SET_CUR	Sets the device state. This sets the active device state; the field values must be the result of a VS_STILL_PROBE_CONTROL(GET_CUR) request. When the associated still-image pipe is active, this attribute cannot be used and the control pipe shall indicate a stall for this request.

4.3.1.3 Synch Delay Control

The purpose for Synch Delay Control is to dynamically synchronize multiple video streams from a device to host, or from multiple devices to the host to compensate for differing latencies among multiple streams. Latency is the internal delay of the source from acquisition to data delivery on the bus.

Only those devices that are capable of video streaming with adjustable delay latency parameters support this control.

The Control is used to notify the video application buffer memory manager on the device to control an internal latency by controlling output timing of the video data to its endpoint.

It is up to the host (video sink) to synchronize streams by scheduling the rendering of samples at the correct moment, taking into account the internal delays of all media streams being rendered.

Table 4-52 Synch Delay Control

Control Selector		VS_SYNCH_DELAY_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**wDelay**	2	Number	Delay from the time that packet should be sent. It is expressed in units of microsecond

4.3.1.4 Still Image Trigger Control

This control notifies the device to begin sending still-image data over the relevant isochronous or bulk pipe. A dedicated still-image bulk pipe is only used for method 3 of still image capture. This control shall only be set while streaming is occurring, and the hardware shall reset it to the "Normal Operation" mode after the still image has been sent. This control is only required if the device supports method 2 or method 3 of still-image retrieval. See section 2.4.2.4 "Still Image Capture".

Table 4-53 Still Image Trigger Control

Control Selector		VS_STILL_IMAGE_TRIGGER_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO		
wLength		1		
Offset	Field	Size	Value	Description
0	**bTrigger**	1	Number	The setting for the Still Image Trigger Control: 0: Normal operation. 1: Transmit still image. 2: Transmit still image via dedicated bulk pipe. 3: Abort still image transmission.

4.3.1.5 Generate Key Frame Control

This control is only supported by devices capable of streaming video with adjustable compression parameters, and support for this control is indicated in the VideoStreaming Header descriptor.

The Generate Key Frame Control is used to notify the video encoder on the device to generate a key frame in the device stream at its earliest opportunity. After the key frame has been generated, the device shall reset the control to the "Normal Operation" mode. This control is only applicable to video formats that support temporal compression (such as MPEG-2 Video), and while streaming is occurring. In all other cases, the device shall respond to requests by indicating a stall on the control pipe.

Table 4-54 Generate Key Frame Control

Control Selector		VS_GENERATE_KEY_FRAME_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_INFO		
wLength		1		
Offset	Field	Size	Value	Description
0	**bGenerateKeyFrame**	1	Number	The setting for the attribute of the addressed Generate Key Frame control: 0: Normal operation 1: Generate Key Frame

4.3.1.6 Update Frame Segment Control

This control is only supported by devices capable of streaming video with adjustable compression parameters, and support for this control is indicated in the VideoStreaming Header descriptor.

The Update Frame Segment Control is used to notify the video encoder on the device to encode the specified range of video frame segments with intra coding (no dependency on surrounding frames) at its earliest opportunity. A video frame segment corresponds to a group of macroblocks that can be decoded independently, such as a slice in MPEG Video, or a Group of Blocks in H.26x Video. This control is only applicable to video formats that support the concept of a video frame segment, and while streaming is occurring. In all other cases, the device shall respond to requests by indicating a stall on the control pipe.

The device will indicate the number of frame segments that it supports through the GET_MAX request, for which the device will indicate the maximum frame segment index supported in both the **bStartFrameSegment** and **bEndFrameSegment** fields. The minimum value for these fields shall always be zero. The resolution for this control should always be set to 1.

Table 4-55 Update Frame Segment Control

Control Selector		VS_UPDATE_FRAME_SEGMENT_CONTROL		
Mandatory Requests		SET_CUR, GET_CUR, GET_MIN, GET_MAX, GET_RES, GET_INFO, GET_DEF		
wLength		2		
Offset	Field	Size	Value	Description
0	**bStartFrameSegment**	1	Number	The zero-based index of the first frame segment in the range to update
1	**bEndFrameSegment**	1	Number	The zero-based index of the last frame

				segment in the range to update

4.3.1.7 Stream Error Code Control

This read-only control indicates the cause of a stream error that may arise during video or still-image transfer. In such cases, the device will update this control with the appropriate code to report the cause of the error.

The host software should send a GET_CUR request to this control to determine the error when one of the following events occurs:

- The Error bit in the video or still image payload header is set by the device (see section 2.4.3.2.2, "Sample Isochronous Transfers").
- The device issues a "Stream Error" interrupt to the host, with the source being the Stream Error Code Control (see section 2.4.2.2, "Status Interrupt Endpoint").
- A bulk video endpoint returns a STALL packet to the host in the data or handshake stage of the transaction.

For scenarios where the host is transmitting video data to the device, the host can not use the Error bit in the payload header to detect a device error. Therefore, in order to determine when a streaming error occurs, the host must rely on either a Control Change interrupt from the device or a bulk endpoint stall.

Table 4-56 Stream Error Code Control

Control Selector		VS_STREAM_ERROR_CODE_CONTROL		
Mandatory Requests		GET_CUR, GET_INFO		
wLength		1		
Offset	Field	Size	Value	Description
0	**bStreamErrorCode**	1	Number	0: No Error. 1: Protected content – This situation occurs if the data source device detects that the video or still-image data is protected and cannot be transmitted. In this case, empty packets containing only headers will be sent for the duration of the protected content. 2: Input buffer underrun – If the data source device is not able to supply data at the requested rate, it will transmit empty packets containing only headers for the duration of the buffer underrun. 3. Data discontinuity - This bit is set if

				there is a data discontinuity (arising from bad media, encoder errors, etc.) preceding the data payload in the current transfer. 4: Output buffer underrun – This bit is set if the data sink device is not being supplied with data at a sufficient rate. 5: Output buffer overrun – This bit is set if the data sink device is being supplied with data at a rate that exceeds its buffering capabilities. 6: Format change – This bit is set if a dynamic format change event occurs. See section 2.4.3.6, "Dynamic Format Change Support". 7: Still image capture error - This bit is set if a device error occurs during still-image capture. 8: Unknown.

Appendix B. Terminal Types

The following is a list of possible Terminal types. This list is non-exhaustive and could be expanded in the future.

B.1. USB Terminal Types

These Terminal types describe Terminals that handle signals carried over the USB, through isochronous or bulk pipes. These Terminal types are valid for both Input and Output Terminals.

Table B- 1 USB Terminal Types

Terminal Type	Code	I/O	Description
TT_VENDOR_SPECIFIC	0x0100	I/O	A Terminal dealing with a signal carried over a vendor-specific interface. The vendor-specific interface descriptor must contain a field that references the Terminal.
TT_STREAMING	0x0101	I/O	A Terminal dealing with a signal carried over an endpoint in a VideoStreaming interface. The VideoStreaming interface descriptor points to the associated Terminal through the **bTerminalLink** field.

B.2. Input Terminal Types

These Terminal Types describe Terminals that are designed to capture video. They either are physically part of the video function or can be assumed to be connected to it in normal operation. These Terminal Types are valid only for Input Terminals

Table B- 2 Input Terminal Types

Terminal Type	Code	I/O	Description
ITT_ VENDOR_SPECIFIC	0x0200	I	Vendor-Specific Input Terminal.
ITT_CAMERA	0x0201	I	Camera sensor. To be used only in Camera Terminal descriptors.
ITT_MEDIA_TRANSPORT_INPUT	0x0202	I	Sequential media. To be used only in Media Transport Terminal Descriptors.

B.3. Output Terminal Types

These Terminal types describe Terminals that are designed to render video. They are either physically part of the video function or can be assumed to be connected to it in normal operation. These Terminal types are only valid for Output Terminals.

Table B- 3 Output Terminal Types

Terminal Type	Code	I/O	Description
OTT_ VENDOR_SPECIFIC	0x0300	O	Vendor-Specific Output Terminal.
OTT_DISPLAY	0x0301	O	Generic display (LCD, CRT, etc.).
OTT_MEDIA_TRANSPORT_OUTPUT	0x0302	O	Sequential media . To be used only in Media Transport Terminal Descriptors.

B.4. External Terminal Types

These Terminal types describe external resources and connections that do not fit under the categories of Input or Output Terminals because they do not necessarily translate video signals to or from the user of the computer. Most of them may be either Input or Output Terminals.

Table B- 4 External Terminal Types

Terminal type	Code	I/O	Description
EXTERNAL_ VENDOR_SPECIFIC	0x0400	I/O	Vendor-Specific External Terminal.
COMPOSITE_CONNECTOR	0x0401	I/O	Composite video connector.
SVIDEO_CONNECTOR	0x0402	I/O	S-video connector.
COMPONENT_CONNECTOR	0x0403	I/O	Component video connector.

Appendix C. Video and Still Image Formats

C.1. Supported video and still image formats

This specification is designed to be format-agnostic, and will support any present or future video or still image format. The video and still image formats supported by the device are reported to the host software via format descriptors (see section 3.9.2.3, "Payload Format Descriptors").

C.2. Proprietary video formats

New or proprietary video and still-image formats must be defined outside of this specification via Payload Format Specifications. . The host software will require a matching video encoder or decoder module.
